Dedicated to Freeman J. Dyson on the occasion of his 80th birthday

Abstract

We continue the study of the two-component charged Bose gas initiated by Dyson in 1967. He showed that the ground state energy for N particles is at least as negative as $-CN^{7/5}$ for large N and this power law was verified by a lower bound found by Conlon, Lieb and Yau in 1988. Dyson conjectured that the exact constant C was given by a mean-field minimization problem that used, as input, Foldy's calculation (using Bogolubov's 1947 formalism) for the one-component gas. Earlier we showed that Foldy's calculation is exact insofar as a lower bound of his form was obtained. In this paper we do the same thing for Dyson's conjecture. The two-component case is considerably more difficult because the gas is very non-homogeneous in its ground state.

1 Introduction

In 1967 Dyson [D] showed that a system composed of non-relativistic, charged bosons is unstable in the sense that the ground state energy of N particles is at least as negative as $-CN^{7/5}$ instead

of $-CN$, where C is some constant. A lower bound of the form $-C'N^{7/5}$ was derived later [CLY], thereby establishing the correctness of the exponent $7/5$, but not the constant C.

In an earlier, parallel development, in 1961 Foldy [F] considered the problem of the one-component Bose gas ("jellium") in which charged particles (all of the same charge) move in a uniformly charged, neutralizing background. Using Bogolubov's 1947 theory [B], Foldy "derived" the high density asymptotics for the ground state energy of this problem as proportional to $-I_0 N \rho^{1/4}$ where I_0 is defined in Eq. (5) below. The correctness of this $\rho^{1/4}$ law, but not the coefficient I_0, was also proved in ([CLY]).

Dyson was motivated by Foldy's work, for he realized that if one treated one of the two components (say, the positive one) as a background for the other, and if one allowed the density to be variable, one would easily arrive — heuristically, at least — at the $N^{7/5}$ law. This will be explained below.

Two obvious questions arise from this earlier work. What is the correct coefficient for the $\rho^{1/4}$ law at high density and what is the correct coefficient for the $N^{7/5}$ law? The former question was resolved by us in [LSo], where we showed that Foldy's I_0 is, indeed, correct at high density as a lower bound. Foldy's calculation is "essentially" an upper bound, meaning that if some technical issues can be resolved then it is an upper bound; these irritating technical issues are still open.

In [D] Dyson derives a rigorous upper bound for the $N^{7/5}$ law, but with a coefficient C that is clearly too small. He conjectures a "correct" coefficient, however, and in the present paper we shall show that Dyson's conjectured coefficient gives a correct lower bound (asymptotically as $N \to \infty$). An asymptotically correct upper bound for the two-component gas energy is still an open problem.

Actually, our lower bound is slightly more general than just the case of $N/2$ particles of each charge. We prove the lower bound for the case in which the total number is N without restriction to the $N/2$, $N/2$ case.

In order to understand the reason that the proof for the two-component case is more difficult than that for jellium, presented in [LSo], it is necessary to recapitulate Dyson's argument briefly. His picture is that there is a local density of particles $\rho(x)$, which has a local energy density given by Foldy's formula, i.e., $I_0 \rho(x)^{5/4}$. One might question whether the jellium energy can be simply taken over to the two-component situation, but it is correct to do so, as our lower bound shows. There is a good reason for this within the Bogolubov theory, as we shall explain in Sect. 3, but let us continue with Dyson's picture now. In addition to the local energy there is also a kinetic energy caused by the variation in ρ, namely $\int |\nabla \sqrt{\rho(x)}|^2 dx$. Such an "envelope" energy is familiar from Thomas-Fermi-Weizsäcker and Gross-Pitaevskii theories, for example.

If this total energy is minimized with respect to ρ we are led to a differential equation in $\sqrt{\rho}$ with the side condition that $\int \rho = N$, but the basic features are clear. The scale length of $\rho(x)$ will be of the order $N^{-1/5}$, the amplitude of ρ will be $N^{8/5}$ and the energy will be $N^{7/5}$. Indeed, if we define $\Phi(x) = N^{-4/5} \sqrt{\rho(N^{-1/5}x)}$ such that $\int \Phi^2 = 1$ then the energy as a function of ρ that we

have to minimize can be rewritten as

$$\tfrac{1}{2}\int_{\mathbb{R}^3}|\nabla\sqrt{\rho}|^2 - I_0\int_{\mathbb{R}^3}\rho^{5/4} = N^{7/5}\left(\tfrac{1}{2}\int_{\mathbb{R}^3}|\nabla\Phi|^2 - I_0\int_{\mathbb{R}^3}\Phi^{5/2}\right),\tag{1}$$

which makes the scaling explicit. We then have to minimize the right side with respect to Φ under the condition $\int\Phi^2 = 1$. The finiteness of this minimum energy is an easy consequence of the Sobolev inequality. The existence of a minimizing Φ is a little harder and follows with the help of rearrangement inequalities. It satisfies a Lane-Emden differential equation for some $\mu > 0$ and all $x \in \mathbb{R}^3$

$$-\Delta\Phi(x) - \tfrac{5}{2}I_0\ \Phi(x)^{3/2} + \mu\Phi(x) = 0.\tag{2}$$

The uniqueness of Φ, up to translations, is harder still. See [K, MS, Z].

Dyson's conjecture is contained in [D, eqs. 104, 105]. The normalization convention and units employed there are not completely clear, but the heuristics leading to (104) is clear. This will be clarified in Sect. 3.

The last topic to discuss in this introduction is the essential difficulty inherent in the two-component problem. As in the jellium proof in [LSo] we decompose space into suitable small boxes and impose Neumann boundary conditions on each. The scale length of these boxes is $N^{-2/5+\varepsilon}$. Using the "sliding argument" of [CLY] we can ignore the Coulomb interaction between different boxes. We must then distribute the N particles in the boxes and what we must prove is that the number in the various boxes has a coarse grained density given by the solution ρ to (1). Since the energy is super concave (i.e., $-N^{7/5}$), the lowest energy is obtained by putting all the N particles in one box. What prevents this from happening is that the boxes are not really totally independent, thanks to the kinetic energy operator. In other words, we must somehow save a little bit of the kinetic energy operator to prevent wild variations in particle density between neighboring boxes.

The conundrum is that the mean-field energy in (1) uses all the kinetic energy, not just some of it. Likewise, to get the intrabox energy (the second term in (1)) we also need the full kinetic energy. The resolution is to split the kinetic energy operator $-\Delta$ into a high-momentum part for use in calculating the intrabox energy and a low-momentum part for use in reproducing the first term in (1). Naturally, error terms will arise and the chief difference between this paper and our earlier jellium paper is centered on the definition of the splitting and the management of the induced error terms.

The proof of the main theorem starts in Sect. 4 where we show how to localize the problem into large boxes of size $L \gg N^{-1/5}$ with Dirichlet boundary conditions. This size is larger than the expected size of the bound complex. The decomposition of the kinetic energy into large and small momentum is carried out in an appendix. It is used in Sect. 5, which localizes further into really small boxes of size $\ell \gg N^{-2/5}$. For the relevance of the scale $N^{-2/5}$ the reader is referred to the heuristic discussion in Sect. 3. The control of the electrostatics using sliding is also discussed in both of these sections. Sect. 6 discusses the ultraviolet and infrared cutoffs of the interaction

potential with control of the errors they introduce. In contrast to the treatment in [LSo] we now need to use the kinetic energy to control the errors caused by the ultraviolet and infrared cutoffs in the potential. Sect. 7 controls all the unimportant parts of the localized Hamiltonian and reduces the problem to Bogolubov's Hamiltonian, which is analyzed in Sect. 8.

Sect. 9 gives the first, simple bound on kinetic energy, local non-neutrality, and an estimate on the local condensation. Sect. 10 improves the estimate on condensation with the help of the method of "localizing large matrices" in [LSo] (and which is reviewed in an appendix). (Recall that in [LSo] we had to reach the final estimate on the various energies by a succession of finer and finer error bounds, each taking the previous bound as input.) In Sect. 11, we give the final bound on the energy in each small box. We have to treat boxes with few particles as well as many particles separately. In Sect. 12 we show how the kinetic energy estimate in the appendix (in which the low momentum kinetic energy *between* boxes leads to a difference energy on a lattice) leads, in turn, to the term $\int |\nabla \sqrt{\rho}|^2$ in the energy functional (1). In the final Sect. 13 all the estimates are put together and we show how to choose the various parameters to get the desired minimization problem for the lower bound.

We thank Y.Y. Li and M.I. Weinstein for pointing out the references [K, MS, Z] to us.

2   Basic definitions and main theorem

We consider N particles with charges $e_i = \pm 1$, $i = 1, \ldots, N$. The Hamiltonian describing the system is

$$H_N = \sum_{i=1}^{N} -\tfrac{1}{2}\Delta_i + \sum_{1 \leq i < j \leq N} \frac{e_i e_j}{|x_i - x_j|} \tag{3}$$

acting on $L^2(\mathbb{R}^{3N})$. We shall not specify the number of positive or negative particles, but simply consider the smallest possible energy

$$E(N) = \inf\{\inf \operatorname{spec}_{L^2(\mathbb{R}^{3N})} H_N \mid e_i = \pm 1, \ i = 1, \ldots, N\}.$$

Instead of considering H_N depending on the parameters $e_1, \ldots, e_N$ we may consider it as *one* operator on the enlarged space $L^2\left((\mathbb{R}^3 \times \{1, -1\})^N\right)$, where the set $\{1, -1\}$ contains the values of the charge variables. Then

$$E(N) = \inf \operatorname{spec}_{L^2((\mathbb{R}^3 \times \{1,-1\})^N)} H_N.$$

Thus $E(N)$ is the infimum of $\langle \Psi, H_N \Psi \rangle$, over normalized functions Ψ in $L^2\left((\mathbb{R}^3 \times \{1, -1\})^N\right)$. Here we may restrict Ψ to be non-negative and thus moreover also to be symmetric under the interchange of particles. Thus $E(N)$ is the energy of a charged Bose gas.

Our main result is an asymptotic lower bound on $E(N)$ which was conjectured by Dyson in [D].

2.1 THEOREM (Dyson's formula). *As $N \to \infty$ we have*

$$E(N) \geq -AN^{7/5} + o(N^{7/5}),$$

where A is the positive constant determined by the variational principle

$$-A = \inf\left\{ \tfrac{1}{2} \int_{\mathbb{R}^3} |\nabla\Phi|^2 - I_0 \int_{\mathbb{R}^3} \Phi^{5/2} \;\middle|\; 0 \leq \Phi, \; \int_{\mathbb{R}^3} \Phi^2 \leq 1 \right\} \tag{4}$$

with

$$I_0 = (2/\pi)^{3/4} \int_0^\infty \left(1 + x^4 - x^2 \left(x^4 + 2 \right)^{1/2} \right) dx = \frac{4^{5/4}\Gamma(3/4)}{5\pi^{1/4}\Gamma(5/4)}. \tag{5}$$

It will be clear from the proof (see the discussion in Sect. 13) that the error in Dyson's formula could have been written in the form $N^{7/5-\xi}$ for some $\xi > 0$. Although this is in principle straightforward we have not attempted to optimize the error term to determine the exact exponent ξ.

3   Heuristic derivation of the energy

In this section we give the heuristic derivation that leads to the local energy density $I_0\rho^{5/4}$ in the second term in (1) (see also (4)). The fact that the constant for the two-component gas is the same as I_0, the constant for the one-component gas, is somewhat mysterious. After all, there is not only the negative $+-$ interaction energy, but there are also the $++$ and $--$ energies. Moreover, the ρ in the two-component case refers to the total number of particles, which is twice the number of each charge (in the neutral case), whereas ρ refers only to the movable particles of one sign in the one-component case.

Another problem is that the usual thermodynamic limit exists for the one-component gas only because we constrain the background to have uniform density and we do not allow it to contract to a high density ball, as it would if one merely minimizes the energy. The two-component gas does not have the usual thermodynamic limit because, as Dyson showed, its energy goes as $-N^{7/5}$.

Nevertheless, we shall describe the two-component charged gas on a small local scale ℓ as a gas of uniform density ρ. For such a uniform gas we shall imitate Foldy's calculation [F] to arrive at the energy $-I_0\rho^{5/4}\ell^3$. We shall assume that $\ell \ll N^{-1/5}$ (the scale on which $\rho(x)$ varies), but $\ell \gg \rho^{-1/4}$ which, as we shall see, is the relevant scale for the uniform gas. Note that we expect $\rho \sim N^{8/5}$ and hence $\rho^{-1/4} \sim N^{-2/5}$. In any event, we are being "heuristic" in this section and the reader is welcome to ignore this "derivation" if it is not pleasing.

We shall use periodic boundary conditions, as usual, and write the Hamiltonian in second quantized form in the manner of Bogolubov/Foldy as

$$H_{\mathrm{F}} \quad = \quad \sum_k \tfrac{1}{2}k^2 \left(a_{k+}^* a_{k+} + a_{k-}^* a_{k-} \right)$$

$$+ \frac{1}{2\ell^3} \sum_{k\neq 0} \sum_{pq} \frac{4\pi}{k^2} \Big(a_{p+}^* a_{q+}^* a_{(q-k)+} a_{(p+k)+} + a_{p-}^* a_{q-}^* a_{(q-k)-} a_{(p+k)-}$$

$$- 2a_{p+}^* a_{q-}^* a_{(q-k)-} a_{(p+k)+} \Big), \tag{6}$$

where the sums are over momenta in the set $\frac{2\pi}{\ell}\mathbb{Z}^3$. Here $a_{p\pm}^*$ creates a state with momentum p and charge ± 1.

In the second term we have excluded $k = 0$, which is also what Foldy does. It would of course be meaningless to include this term and leave the Fourier transform of the potential equal to $\frac{4\pi}{k^2}$. If, instead, we defined the Fourier transform of the potential for $k = 0$ to be proportional to ℓ^2 (which is the maximal value of the Fourier transform for $k \neq 0$), the contribution from the term $k = 0$ would be proportional to $-(\rho\ell^3)\ell^{-1}$ for a neutral system. If, as we assume, $\ell \gg \rho^{-1/4}$ then $(\rho\ell^3)\ell^{-1} \ll \rho^{5/4}\ell^3$. Hence we may ignore the $k = 0$ contribution. In Foldy's situation the corresponding term would not contribute to the thermodynamic limit.

The next step in the heuristic derivation is to exclude those terms in the second sum above that do not contain precisely two creation or annihilation operators of particles of momentum zero. Subsequently these zero momentum creation or annihilation operators $a_{0\pm}^*$ and $a_{0\pm}$ are replaced by the square root of half the particle number, namely $\sqrt{\rho\ell^3/2}$. We then arrive at

$$\sum_k \tfrac{1}{4}k^2 \left(a_{k+}^* a_{k+} + a_{-k+}^* a_{-k+} + a_{k-}^* a_{k-} + a_{-k-}^* a_{-k-} \right)$$

$$+ \frac{\rho}{4} \sum_{k\neq 0} \frac{4\pi}{k^2} \Big[a_{k+}^* a_{k+} + a_{-k+}^* a_{-k+} + a_{k+}^* a_{-k+}^* + a_{k+} a_{-k+}$$

$$+ a_{k-}^* a_{k-} + a_{-k-}^* a_{-k-} + a_{k-}^* a_{-k-}^* + a_{k-} a_{-k-}$$

$$- \left(a_{k+}^* a_{k-} + a_{-k+}^* a_{-k-} + a_{k-}^* a_{k+} + a_{-k-}^* a_{-k+} \right.$$

$$\left. a_{k+}^* a_{-k-}^* + a_{-k+}^* a_{k-}^* + a_{k+} a_{-k-} + a_{-k+} a_{k-} \right) \Big].$$

This expression should be compared with Lemma 8.1, where we arrive at a similar expression as a rigorous lower bound on part of the full Hamiltonian. (In comparing with the lemma one should replace $b_k \to a_k$, $\nu^+, \nu^- \to \rho\ell^3/2$, $\hat{V}_{r,R}(k) \to \frac{4\pi}{|k|^2}$, $\gamma_{\varepsilon,t} \to 1$, $(\ell t^6)^{-2} \to 0$, and of course also $\frac{\ell^3}{(2\pi)^3} \int dk \to \sum_k$.)

The final step is to recognize that the resulting quadratic Hamiltonian has the following property, as the reader can easily check: The operators $a_{k\pm}$ always appear in the potential energy term (the last sum above) in the combination $d_k = (a_{k+} - a_{k-})/\sqrt{2}$. This is a normal mode since $[d_k, d_q^*] = \delta_{k,q}$. The other normal mode $c_k = (a_{k+} + a_{k-})/\sqrt{2}$ appears only in the kinetic energy term (the first sum above), i.e., the kinetic energy is $a_{k+}^* a_{k+} + a_{k-}^* a_{k-} = c_k^* c_k + d_k^* d_k$. The ground state is achieved by having no c_k excitations, which leaves us just with the term $d_k^* d_k$ in the kinetic energy term.

The conclusion is that the quadratic Hamiltonian is now exactly the same as Foldy's (but with d_k in place of a_k) and, therefore, the ground state energy is $-I_0\rho^{5/4}\ell^3$. This conclusion could also have been arrived at by an explicit diagonalization of the total quadratic Hamiltonian. (See Sect. 8, in particular Theorem 8.2, for comparison.)

The detailed diagonalization analysis shows that the relevant momenta k are of magnitude $\rho^{1/4}$ and hence as mentioned above the relevant length scale is $\rho^{-1/4}$. The assumption $\ell \gg \rho^{-1/4}$ allows one to replace sums over the lattice $\frac{2\pi}{\ell}\mathbb{Z}^3$ by integrals $\frac{\ell^3}{(2\pi)^3}\int_{\mathbb{R}^3} dk$. This is how the integral in (5) appears.

4   Localization

If Dyson's conjecture is correct then the size of the boson cloud is proportional to $N^{-1/5}$. As a first step we shall localize the problem into cubes of size L, where we choose L as a function of N in such a way that $N^{1/5}L \to \infty$ as $N \to \infty$. Exactly how $N^{1/5}L \to \infty$ will be determined at the end of the analysis in Sect. 13. As a consequence of our results we shall see that essentially all particles will concentrate within one of these cubes of size L.

We shall do the localization in such a way that the cubes do not interact and the analysis can be done in each cube independently. The only thing to bear in mind is that the total number of particles in all cubes is N.

In analyzing the individual cubes we shall perform a further localization into smaller cells of a size $\ell < L$ depending on N in such a way that $N^{2/5}\ell \to \infty$ as $N \to \infty$ (precisely how will again be determined in Sect. 13).

We shall first describe how we control the electrostatic interaction between the different regions into which we localize. We do this in a manner very similar to what was done in [LSo] using the sliding technique of [CLY], and shall use this technique both for the localization into the large cubes and again when we localize into the smaller cells.

Let t, with $0 < t < 1/2$, be a parameter which will be chosen later in Sect. 13 to depend on N in such a way that $t \to 0$ as $N \to \infty$.

Let $\Theta, \theta \in C_0^\infty(\mathbb{R}^3)$ satisfy

1. $0 \le \Theta, \theta \le 1$, $\theta(x) = \theta(-x)$, and $\Theta(x) = \Theta(-x)$.

2. supp $\theta \subset [(-1+t)/2, (1-t)/2]^3$, supp $\Theta \subset [(-1-t)/2, (1+t)/2]^3$.

3. $\theta(x) = 1$ for $x \in [(-1+2t)/2, (1-2t)/2]^3$, and $\Theta(x) = 1$ for $x \in [(-1+t)/2, (1-t)/2]^3$,

4. All derivatives of order m for $m \le 3$ of the functions $\theta, \sqrt{1-\theta^2}, \Theta$ are uniformly bounded by Ct^{-m}, where C is some universal constant.

5. For all $x \in \mathbb{R}^3$ we have $\sum\limits_{k \in \mathbb{Z}^3} \Theta(x-k)^2 = 1$.

We introduce the two constants γ, $\widetilde{\gamma}$ such that $\gamma \int \theta(y)^2 dy = 1$ and $\widetilde{\gamma} \int \Theta^4(y)^2 dy = 1$. Then

$$1 \leq \gamma \leq (1 - 2t)^{-3}, \quad (1 + t)^{-3} \leq \widetilde{\gamma} \leq (1 - t)^{-3}. \tag{7}$$

We also introduce the Yukawa potential $Y_m(x) = |x|^{-1} e^{-m|x|}$ for $m \geq 0$. For $m = 0$ this is, of course, the Coulomb potential.

4.1 LEMMA (Electrostatic decoupling of boxes using sliding).
There exists a function of the form $\omega(t) = Ct^{-4}$ (we assume that $\omega(t) \geq 1$ for $t < 1/2$) such that for all $x_1, x_2, \ldots, x_N \in \mathbb{R}^3$, all $e_1, e_2, \ldots, e_N$, with $|e_i| = 1$ for $i = 1, 2, \ldots, N$, all $m \geq 0$, and all $\lambda > 0$ we have

$$\sum_{1 \leq i < j \leq N} e_i e_j Y_m(x_i - x_j) \geq \gamma \int_{\mathbb{R}^3} \sum_{1 \leq i < j \leq N} e_i e_j \theta\left(\frac{x_i}{\lambda} - z\right) Y_{m + \frac{\omega(t)}{\lambda}}(x_i - x_j) \theta\left(\frac{x_j}{\lambda} - z\right) dz - \frac{N\omega(t)}{2\lambda} \tag{8}$$

and likewise

$$\sum_{1 \leq i < j \leq N} e_i e_j Y_m(x_i - x_j) \geq \widetilde{\gamma} \int_{\mathbb{R}^3} \sum_{1 \leq i < j \leq N} e_i e_j \Theta^2\left(\frac{x_i}{\lambda} - z\right) Y_{m + \frac{\omega(t)}{\lambda}}(x_i - x_j) \Theta^2\left(\frac{x_j}{\lambda} - z\right) dz - \frac{N\omega(t)}{2\lambda}. \tag{9}$$

Proof. Since θ and Θ^2 have the same properties it is enough to consider θ. By rescaling we may assume that $\lambda = 1$. We have that

$$\int \gamma\theta(x - z) Y_{m+\omega}(x - y) \theta(y - z) \, dz = h(x - y) Y_{m+\omega}(x - y),$$

where we have set $h = \gamma\theta * \theta$. We chose γ such that $1 = h(0) = \gamma \int \theta(y)^2 \, dy$. Then h satisfies all the assumptions in Lemma 2.1 in [CLY]. We then conclude from Lemma 2.1 in [CLY] that the Fourier transform of the function $F(x) = Y_m(x) - h(x) Y_{m+\omega}(x)$ is non-negative, if ω is chosen large enough depending on h. [The detailed bounds from [CLY] show that we may in fact choose $\omega = Ct^{-4}$, since ω has to control the 4th derivative of h.] Note, moreover, that $\lim_{x \to 0} F(x) = \omega$. Hence

$$\sum_{1 \leq i < j \leq N} e_i e_j F(y_i - y_j) \geq -\sum_{i=1}^{N} \frac{e_i^2 \omega}{2} = -\frac{N\omega}{2}.$$

The lemma follows by writing $Y_m(x) = F(x) + h(x) Y_{m+\omega}(x)$. $\square$

We shall use the electrostatic decoupling (9) when we localize into the large cubes of size L and then (8) when we localize further into the smaller cells. We begin with the localization into large cubes.

4.2 THEOREM (Localization into a large cube). *Let*

$$H_{N,L} = \sum_{i=1}^{N} -\tfrac{1}{2}\Delta_{i,\mathrm{D}} + \sum_{1 \leq i < j \leq N} e_i e_j \widetilde{\gamma} Y_{\frac{\omega(t)}{L}}(x_i - x_j)$$

be a Hamiltonian acting in the space $L^2\left(([-L/2, L/2]^3 \times \{1, -1\})^N\right)$. Here Δ_{D} refers to the Dirichlet Laplacian in the cube $[-L/2, L/2]^3$. Let

$$E_L(N) = \inf \mathrm{spec} H_{N,L}. \tag{10}$$

Then

$$E(N) \geq E_L(N) - N^{7/5}\left(Ct^{-2}(N^{1/5}L)^{-2} + \tfrac{1}{2}\omega(t)N^{-1/5}(N^{1/5}L)^{-1}\right).$$

Proof. For all $z \in \mathbb{R}^3$ let $\Theta_z(x) = \Theta((x/L) - z)$. We consider Θ_z as a multiplication operator on $L^2(\mathbb{R}^3)$. We have for all $z \in \mathbb{R}^3$ that

$$\sum_{k \in \mathbb{Z}^3} \Theta_{z+k}^2(x) = 1.$$

Using (9) with $m = 0$ and that $\int_{\mathbb{R}^3} f(z)dz = \sum_{k \in \mathbb{Z}^3} \int_{[-1/2,1/2]^3} f(z+k)dz$ we see that

$$\sum_{1 \leq i < j \leq N} \frac{e_i e_j}{|x_i - x_j|}$$

$$\geq \sum_{\mathbf{k}=(k_1,\ldots,k_N) \in \mathbb{Z}^{3N}} \int_{[-1/2,1/2]^3} F_{\mathbf{k},z}(x_1,\ldots,x_N)^2 \sum_{1 \leq i < j \leq N} \delta_{k_i k_j} e_i e_j \widetilde{\gamma} Y_{\omega(t)/L}(x_i - x_j)\, dz - \frac{N\omega(t)}{2L},$$

where

$$F_{\mathbf{k},z}(x_1,\ldots,x_N) = \Theta_{k_1+z}(x_1)\cdots\Theta_{k_N+z}(x_N), \quad \mathbf{k} = (k_1,\ldots,k_N) \in \mathbb{Z}^{3N}.$$

We localize the kinetic energy using the formula

$$-\Delta = \sum_{k \in \mathbb{Z}^3} \Theta_{z+k}(-\Delta)\Theta_{z+k} - \sum_{k \in \mathbb{Z}^3} (\nabla\Theta_{z+k})^2 \geq \sum_{k \in \mathbb{Z}^3} \Theta_{z+k}(-\Delta)\Theta_{z+k} - C(tL)^{-2},$$

which gives

$$\sum_{i=1}^N -\Delta_i \geq \sum_{\mathbf{k} \in \mathbb{Z}^{3N}} \int_{[-1/2,1/2]^3} F_{\mathbf{k},z}(x_1,\ldots,x_N) \sum_{i=1}^N (-\Delta_i) F_{\mathbf{k},z}(x_1,\ldots,x_N)\, dz - CN(tL)^{-2}.$$

The previous estimates imply that

$$H_N \geq \sum_{\mathbf{k} \in \mathbb{Z}^{3N}} \int_{[-1/2,1/2]^3} F_{\mathbf{k},z}(x_1,\ldots,x_N) \sum_{k \in \mathbb{Z}^3} H_{\mathbf{k},z}^{(k)} F_{\mathbf{k},z}(x_1,\ldots,x_N)\, dz - \frac{N\omega(t)}{2L} - CN(tL)^{-2},$$

where we have introduced the operator

$$H_{\mathbf{k},z}^{(k)} = \sum_{\substack{i \\ k_i = k}} -\tfrac{1}{2}\Delta_{i,\mathrm{D}}^{(k+z)} + \sum_{\substack{1 \leq i < j \leq N \\ k_i = k_j = k}} e_i e_j \widetilde{\gamma} Y_{\omega(t)/L}(x_i - x_j)$$

where $\Delta_{\mathrm{D}}^{(k+z)}$ denotes the Dirichlet Laplacian in the cube $\{(k+z)L\} + [-L/2, L/2]^3$. Note that the operator $H_{\mathbf{k},z}^{(k)}$ above acts on functions for which the space variables are in the set $\{(k+z)L\} + [-L/2, L/2]^3$. The operator $H_{\mathbf{k},z}^{(k)}$ is hence unitary equivalent to $H_{N,L}$ with N replaced by

$$N_k(k_1,\ldots,k_N) = \#\{i \mid k_i = k\}.$$

We therefore get the lower bound

$$H_N \geq \sum_{\mathbf{k} \in \mathbb{Z}^{3N}} \int_{[-1/2,1/2]^3} F_{\mathbf{k},z}(x_1,\ldots,x_N)^2 \sum_{k \in \mathbb{Z}^3} E_L(N_k(\mathbf{k})) dz - \frac{N\omega(t)}{2L} - CN(tL)^{-2}.$$

The theorem follows if we can prove that

$$\sum_{k \in \mathbb{Z}^3} E_L(N_k(k_1,\ldots,k_N)) \geq E_L(N). \tag{11}$$

To conclude (11), let ψ_k be a normalized N_k-particle ground state eigenfunction of $H_{N_k,L}$, such that

$$(\psi_k, H_{N_k,L}\psi_k) = E_L(N_k).$$

(A normalized 0-particle function we consider simply to be the number 1.) Define the N-particle eigenfunction

$$\Psi(x_1, e_1, \ldots, x_N, e_N) = \prod_k \psi_k((x_i, \tau_k e_i) \mid k_i = k),$$

where we shall choose $\tau_k \in \{1, -1\}$. We then find that

$$(\Psi, H_{N,L}\Psi) = \sum_{k \in \mathbb{Z}^3} E_L(N_k) + \tfrac{1}{2} \sum_{k \neq k'} \tau_k \tau_{k'} I_{kk'}, \tag{12}$$

(note that that there are only finitely many non-zero terms in the sums) where

$$I_{kk'} = \left(\psi_k \psi_{k'}, \sum_{\substack{i \\ k_i = k}} \sum_{\substack{j \\ k_j = k'}} e_i e_j \widetilde{\gamma} Y_{\omega(t)/L}(x_i - x_j) \psi_k \psi_{k'} \right).$$

It is now easy to see that by an appropriate choice of the finite number of parameters τ_k, we can make sure that the last sum in (12) is non-positive. In fact, if we average over all possible choices of $\tau_k = \pm 1$ the last sum in (12) averages to 0.

The estimate (11) is now a consequence of the variational principle. $\qquad\square$

The rest of the analysis is concerned with estimating the energy $E_L(N)$ from (10). As explained in the beginning we may define $E_L(N)$ as $\inf \operatorname{spec} H_{N,L}$ when we consider $H_{N,L}$ as an operator on the *symmetric* tensor product $\bigotimes_S^N L^2([-L/2, L/2]^3 \times \{1, -1\})$.

In the space $\bigotimes_S^N L^2(\mathbb{R}^3 \times \{1, -1\})$ we shall use the notation of second quantization. If $u \in L^2(\mathbb{R}^3 \times \{1, -1\})$ then $a^*(u)$ denotes the creation operator in the Fock space $\bigoplus_{N=0}^{\infty} \bigotimes_S^N L^2(\mathbb{R}^3 \times \{1, -1\})$. Products of the form $a_0^*(u)a_0(u')$ or $a_0(u')a_0^*(u)$ are however bounded operators on each of the fixed particle number spaces $\bigotimes_S^N L^2(\mathbb{R}^3 \times \{1, -1\})$. We may consider $H_{N,L}$ as acting in this space but restricted to functions with support in $([-L/2, L/2]^3 \times \{1, -1\})^N$.

If $u \in L^2(\mathbb{R}^3)$ we use the notation $a_\pm^*(u)$ for the creation operator which creates the function u with charge ± 1 respectively, i.e., the function u defined on $\mathbb{R}^3 \times \{1\}$ or $\mathbb{R}^3 \times \{-1\}$ respectively.

5 The localization of the operator $H_{N,L}$

We turn to the second localization into smaller cubes of size $\ell > 0$, where we shall choose ℓ as a function of N in such a way that $\ell \leq L$ and $N^{2/5}\ell \to \infty$ as $N \to \infty$. As mentioned the precise choice of ℓ as a function of N will be made at the end of section 13 when we complete the proof of Dyson's formula.

Localizing the kinetic energy is difficult. In the paper [LSo] we used Neumann boundary conditions on the small cubes. In this way we got a lower bound by studying independent small boxes. In the present situation we will not get the correct answer if we bound the kinetic energy below by Neumann energies in independent boxes. As explained the "kinetic energy" between boxes is important. A lower bound on the kinetic energy which both contains a contribution from within each box and a contribution that connects boxes is given in Appendix B. We shall use this result now.

We use the function θ to do the localization. For $z \in \mathbb{R}^3$ we define $\chi_z(x) = \theta((x/\ell) - z)$. Then supp $\chi_z \subset \{z\ell\} + [(-1+t)\ell/2, (1-t)\ell/2]^3$. Let $\eta_z = \sqrt{1-\chi_z^2}$. Then $\|\partial^\alpha \chi_z\|_\infty \leq C(\ell t)^{-|\alpha|}$ and $\|\partial^\alpha \eta_z\|_\infty \leq C(\ell t)^{-|\alpha|}$ for all multi-indices α with $|\alpha| \leq 3$.

Let X_z be the characteristic function of the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$, i.e., $X_z(x) = X_0(x - \ell z)$. Let $\mathcal{P}_z$ denote the projection onto the subspace of $L^2\left(\left(\{z\ell\} + [-\ell/2, \ell/2]^3\right) \times \{1, -1\}\right)$ consisting of functions orthogonal to constants. We shall consider $\mathcal{P}_z$ as a projection in $L^2(\mathbb{R}^3 \times \{1, -1\})$. We define for each $z \in \mathbb{R}^3$ the operator

$$\mathcal{K}^{(z)} = \mathcal{P}_z \chi_z \frac{(-\Delta)^2}{-\Delta + (\ell t^6)^{-2}} \chi_z \mathcal{P}_z. \tag{13}$$

The operators $\mathcal{K}^{(z)}$ shall play the role of the kinetic energy within each box.

Let $a_{0\pm}^*(z)$ be the creation operators

$$a_{0\pm}^*(z) = a_\pm^*(\ell^{-3/2} X_z), \tag{14}$$

i.e., the operator creating the constants in the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$. We introduce the notation

$$\widehat{n}_z^\pm = a_{0\pm}^*(z) a_{0\pm}(z) \quad \text{and} \quad \widehat{n}_z = \widehat{n}_z^+ + \widehat{n}_z^-. \tag{15}$$

We refer to $\widehat{n}_z$ as the *number of particles in the condensate* in the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$. The operator for the *total number of particles* in the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$ is

$$\widehat{\nu}_z = \sum_{i=1}^N X_z(x_i) \tag{16}$$

The operators $\widehat{\nu}_z^\pm$ for the total numbers of positively and negatively charged particles are determined by

$$\widehat{\nu}_z^+ + \widehat{\nu}_z^- = \widehat{\nu}_z \quad \text{and} \quad \widehat{\nu}_z^+ - \widehat{\nu}_z^- = \sum_{i=1}^N e_i X_z(x_i).$$

We refer to $\widehat{\nu}_z - \widehat{n}_z$ as the *number of excited particles.*

The kinetic energy that connects boxes will be a type of lattice Laplacian. In fact, for a map $S : \mathbb{Z}^3 \to \mathbb{R}$ we define a lattice Laplacian

$$T(S) = \sum_{\substack{\sigma_1, \sigma_2 \in \mathbb{Z}^3 \\ |\sigma_1 - \sigma_2| = \sqrt{2}}} \frac{1}{12}(S(\sigma_1) - S(\sigma_2))^2 + \sum_{\substack{\sigma_1, \sigma_2 \in \mathbb{Z}^3 \\ |\sigma_1 - \sigma_2| = \sqrt{3}}} \frac{1}{24}(S(\sigma_1) - S(\sigma_2))^2. \tag{17}$$

This specific form of T has been chosen because it is convenient when we shall later compare with a continuum Laplacian (see Sect. 12).

Using Theorem B.1 in Appendix B with $\Omega = [-(L+\ell)/(2\ell), (L+\ell)/(2\ell)]^3$ we obtain the following result.

5.1 LEMMA (Kinetic energy localization). *If* $\Psi \in \bigotimes_S^N L^2(\mathbb{R}^3 \times \{1, -1\})$ *is normalized and has support in* $\left([-L/2, L/2]^3 \times \{1, -1\}\right)^N$ *then for all* $\varepsilon > 0$, $0 < t < 1/2$

$$(1 + \varepsilon + Ct^3)\left(\Psi, \sum_{i=1}^N -\Delta_i \Psi\right) \geq \int_{z \in [-1/2, 1/2]^3} \left(\Psi, \sum_{\sigma \in \mathbb{Z}^3} \sum_{i=1}^N \left(\mathcal{K}_i^{(z+\sigma)} - \varepsilon \Delta_{i,\mathrm{Neu}}^{(z+\sigma)}\right)\Psi\right) + T(S_z^\Psi)\, dz$$
$$-CL^3/\ell^5,$$

where $-\Delta_{\mathrm{Neu}}^{(z)}$ *is the Neumann Laplacian for the cube* $\{z\ell\} + [-\ell/2, \ell/2]^3$ *and* $S_z^\Psi : \mathbb{Z}^3 \to \mathbb{R}$ *is the map*

$$S_z^\Psi(\sigma) = \ell^{-1}\left(\sqrt{\langle \widehat{n}_{z+\sigma}^+ + \widehat{n}_{z+\sigma}^- \rangle + 1} - 1\right) = \ell^{-1}\left(\sqrt{\langle \widehat{n}_{z+\sigma}\rangle + 1} - 1\right), \tag{18}$$

where

$$\langle \widehat{n}_{z+\sigma}^+ + \widehat{n}_{z+\sigma}^- \rangle = \left(\Psi, (\widehat{n}_{z+\sigma}^+ + \widehat{n}_{z+\sigma}^-)\Psi\right).$$

In order to arrive at this lemma from Theorem B.1 we have used the inequality

$$T(S_z) \leq \langle T(S_z^+) + T(S_z^-)\rangle,$$

where $S_z^\pm(\sigma) = \ell^{-1}\sqrt{\widehat{n}_{z+\sigma}^\pm + 1/2}$. To prove this inequality first note that by the 2-dimensional triangle inequality

$$\left(\sqrt{S_1^2 + \widetilde{S}_1^2} - \sqrt{S_2^2 + \widetilde{S}_2^2}\right)^2 \leq (S_1 - S_2)^2 + (\widetilde{S}_1 - \widetilde{S}_2)^2, \tag{19}$$

for all $S_1, S_2, \widetilde{S}_1, \widetilde{S}_2 \in \mathbb{R}$. The estimate (19) implies, in particular, that

$$n \mapsto T(\ell^{-1}\sqrt{n+1} - 1)$$

is a convex map on non-negative functions $n : \mathbb{Z}^3 \to \mathbb{R}$. Hence

$$T(S_z) = T(\ell^{-1}\sqrt{\langle \widehat{n}_{z+\sigma}\rangle + 1} - 1) \leq \langle T(\ell^{-1}\sqrt{\widehat{n}_{z+\sigma} + 1} - 1)\rangle \leq \langle T(S_z^+) + T(S_z^-)\rangle,$$

where the last inequality is again a consequence of (19).

As before we use the sliding technique to localize the electrostatic energy. If we combine Lemma 4.1 and Lemma 5.1 we obtain for $\Psi \in \bigotimes_S^N L^2(\mathbb{R}^3 \times \{1, -1\})$ normalized and with support in $\left([-L/2, L/2]^3 \times \{1, -1\}\right)^N$ that

$$
\begin{aligned}
(\Psi, H_{N,L}\Psi) \geq\ & \gamma\widetilde{\gamma} \int_{z \in [-1/2,1/2]^3} \left(\Psi, \left(\sum_{\sigma \in \mathbb{Z}^3} \widetilde{H}_{z+\sigma} + \frac{\gamma_{\varepsilon,t}}{2} T(S_z)\right) \Psi\right) dz \\
& - CL^3/\ell^5 - \omega(t)N\left(\frac{1}{2\ell} - \frac{1}{2L}\right)
\end{aligned}
\tag{20}
$$

where

$$
\gamma_{\varepsilon,t} = (1 + \varepsilon + Ct^3)^{-1}(\widetilde{\gamma}\gamma)^{-1}
\tag{21}
$$

(recall that γ and $\widetilde{\gamma}$ also depend on t) and for $z \in \mathbb{R}^3$ we have introduced the operator

$$
\widetilde{H}_z = \sum_{i=1}^N \left(\frac{\gamma_{\varepsilon,t}}{2}\mathcal{K}_i^{(z)} - \frac{\gamma_{\varepsilon,t}}{2}\varepsilon\Delta_{i,\mathrm{Neu}}^{(z)}\right) + \sum_{1 \leq i < j \leq N} e_i e_j w_z(x_i, x_j),
\tag{22}
$$

with

$$
w_z(x_i, x_j) = \chi_z(x_i) Y_{\frac{\omega(t)}{\ell}}(x_i - x_j)\chi_z(x_j).
\tag{23}
$$

We shall choose ε depending on N in Sect. 13 in such a way that $\varepsilon \to 0$ as $N \to \infty$. We shall in particular assume that $\varepsilon < 1$. Hence we may assume that $\gamma_{\varepsilon,t}$ is bounded above and below by constants.

The expressions $\left(\Psi, \sum_{\sigma \in \mathbb{Z}^3} \widetilde{H}_{z+\sigma}\Psi\right) + \frac{1}{2}\gamma_{\varepsilon,t}T(S_z^\Psi)$ are equivalent for the different $z \in [-1/2, 1/2]^3$. It is therefore enough to consider $z = 0$. Moreover, the operator $\sum_{\sigma \in \mathbb{Z}^3} \widetilde{H}_\sigma$ commutes with the number operators $\widehat{\nu}_\sigma^\pm$ (the operators giving the number of positively and negatively charged particles in the cube $\{\ell\sigma\} + [-\ell/2, \ell/2]^3$). Note that if Ψ has support in the set $\left([-L/2, L/2]^3 \times \{1, -1\}\right)^N$ then for z outside the set $\Omega = [-\frac{L}{2\ell} - \frac{1}{2}, \frac{L}{2\ell} + \frac{1}{2}]^3$ we have that Ψ is in the kernel of the operators $\widehat{\nu}_z^\pm$.

The estimate (20) then implies the following result.

5.2 THEOREM (Localization into small cubes). *With the definitions from (10),(13–18), and (21–23) we have that*

$$
E_L(N) \geq \gamma\widetilde{\gamma} \inf_{\Psi, \|\Psi\|=1} \left(\left(\Psi. \sum_{\sigma \in \mathbb{Z}^3} \widetilde{H}_\sigma\Psi\right) + \frac{\gamma_{\varepsilon,t}}{2} T(S_0^\Psi)\right) - CL^3/\ell^5 - \omega(t)N\left(\frac{1}{2\ell} - \frac{1}{2L}\right),
$$

where the infimum is over normalized functions

$$
\Psi \in \mathcal{H}_0 = \left\{\Psi \in \bigotimes_S^N L^2(\mathbb{R}^3 \times [-1, 1])\,\Big|\, \widehat{\nu}_\sigma^\pm\Psi = 0 \text{ for } \sigma \notin \mathbb{Z}^3 \cap \left[-\frac{L}{2\ell} - \frac{1}{2}, \frac{L}{2\ell} + \frac{1}{2}\right]^3\right\},
$$

and $0 < t < 1/2$ is the parameter from the beginning of Sect. 4.

In the following Sects. 6–11 we shall study the operators $\widetilde{H}_\sigma$, $\sigma \in \mathbb{Z}^3$. Since $\widetilde{H}_\sigma$ commutes with $\widehat{\nu}_\sigma^\pm$ we may simply restrict to the eigenspaces of $\widehat{\nu}_\sigma^\pm$. We shall therefore not think of $\widehat{\nu}_\sigma^\pm$ and $\widehat{\nu}_\sigma$ as operators, but as classical parameters $\nu_\sigma^\pm$ and ν_σ. Which values of these parameters that will give the optimal energy is of course not known a-priori, but they must satisfy $\sum_\sigma \nu_\sigma = N$. The operator $\widetilde{H}_\sigma$ is in (22) written as an N-particle operator, but it depends only on ν_σ particles. We shall therefore simply think of it as a ν_σ-particle operator. The operators $\widetilde{H}_\sigma$ for different σ are all unitarily equivalent. We shall in Sects. 6–11 simply omit the subscript σ.

6   Long and short distance cutoffs in the potential

Our aim in this section is to replace w in (23) (omitting the index z) by a function that has long and short distance cutoffs.

We shall replace the function w by

$$w_{r,R}(x,y) = \chi(x)V_{r,R}(x-y)\chi(y) \tag{24}$$

where

$$V_{r,R}(x) = Y_{R^{-1}}(x) - Y_{r^{-1}}(x) = \frac{e^{-|x|/R} - e^{-|x|/r}}{|x|} \tag{25}$$

Here $0 < r \le R \le \omega(t)^{-1}\ell$. Note that for $x \ll r$ then $V_{r,R}(x) \approx r^{-1} - R^{-1}$ and for $|x| \gg R$ then $V_{r,R}(x) \approx |x|^{-1}e^{-|x|/R}$.

We first introduce the cutoff R alone, i.e., we bound the effect of replacing w by $w_R(x,y) = \chi(x)V_R(x-y)\chi(y)$, where $V_R(x) = |x|^{-1}e^{-|x|/R} = Y_{R^{-1}}(x)$. Thus, since $R \le \omega(t)^{-1}\ell$, the Fourier transforms satisfy

$$\widehat{Y}_{\omega/\ell}(k) - \widehat{V}_R(k) = 4\pi \left(\frac{1}{k^2 + (\omega(t)/\ell)^2} - \frac{1}{k^2 + R^{-2}} \right) \ge 0.$$

(We use the convention that $\hat{f}(k) = \int f(x)e^{-ikx}\,dx$.) Hence

$$w(x,y) - w_R(x,y) = \chi(x)\left(Y_{\omega/\ell} - V_R\right)(x-y)\chi(y)$$

defines a positive semi-definite kernel. Note, moreover, that $\left(Y_{\omega/\ell} - V_R\right)(0) = R^{-1} - \omega/\ell \le R^{-1}$. Thus,

$$
\begin{aligned}
\sum_{1 \le i < j \le N} e_i e_j (w(x_i,x_j) - w_R(x_i,x_j)) &= \frac{1}{2} \sum_{1 \le i,j \le N} e_i e_j (w - w_R)(x_i,x_j) \\
&\quad - \sum_{i=1}^N \frac{e_i^2}{2}(w - w_R)(x_i,x_i) \\
&\ge -\tfrac{1}{2}\nu \left(Y_{\omega/\ell} - V_R\right)(0) \ge -\tfrac{1}{2}\nu R^{-1}.
\end{aligned}
\tag{26}
$$

Here we have used that $\sum_{i=1}^N \chi(x_i)^2 \le \sum_{i=1}^N X(x_i) = \nu$.

We shall now bound the effect of replacing w_R by $w_{r,R}$. I.e., we are replacing $V_R(x) = |x|^{-1}e^{-|x|/R}$ by $|x|^{-1}\left(e^{-|x|/R} - e^{-|x|/r}\right)$. The correction is $Y_{r^{-1}}(x) = |x|^{-1}e^{-|x|/r}$.

6.1 LEMMA. *We have for all $\delta > 0$ the operator inequality*

$$\sum_{i=1}^{N} -\frac{\delta}{2}\Delta_{i,\text{Neu}}^{(z)} + \sum_{1 \leq i < j \leq N} e_i e_j \chi(x_i) Y_{r^{-1}}(x_i - x_j)\chi(x_j) \geq -C\nu^+\nu^-(r^2\ell^{-3} + \delta^{-3/2}r^{1/2}).$$

Proof. We set $z = 0$ and omit the index z in this proof. For $D > 0$ we define

$$W_D(x) = \begin{cases} Y_{r^{-1}}(D), & |x| < D \\ Y_{r^{-1}}(x), & |x| \geq D \end{cases}.$$

Then the measure

$$\mu_D = (4\pi)^{-1}(-\Delta + r^{-2})W_D = (4\pi)^{-1}r^{-2}Y_{r^{-1}}(D)\mathbf{1}_{|x|<D} - (4\pi)^{-1}Y'_{r^{-1}}(D)\delta(|x| - D)$$

is non-negative and $W_D = \mu_D * Y_{r^{-1}}$. Here $Y'_{r^{-1}}$ refers to the radial derivative of $Y_{r^{-1}}$ and $\mathbf{1}_{|x|<D}$ is the characteristic function of the set $\{|x| < D\}$.

Define the (signed) measure

$$d\mu(x) = \sum_{i=1}^{N} e_i \chi(x_i) d\mu_{D_i}(x - x_i),$$

where

$$D_i = \tfrac{1}{2}\min\left\{|x_i - x_j| \mid j = 1, \ldots, N, \ e_i e_j = -1, \ x_i \in [-\ell/2, \ell/2]^3\right\},$$

is half the distance from the particle at x_i to the nearest particle of opposite charge in the cube $[-\ell/2, \ell/2]^3$, i.e., the cube in which χ is supported. Thus for $x_i, x_j \in [-\ell/2, \ell/2]^3$ we have

$$\begin{aligned}
\iint Y_{r^{-1}}(x - y)d\mu_{D_i}(x - x_i)d\mu_{D_j}(y - x_j) &= \int W_{D_j}(x - x_j)d\mu_{D_i}(x - x_i) \\
&\leq \int Y_{r^{-1}}(x - x_j)d\mu_{D_i}(x - x_i) \\
&= W_{D_i}(x_i - x_j) \leq Y_{r^{-1}}(x_i - x_j)
\end{aligned}$$

and both inequalities become equalities if $e_i e_j = -1$. Hence

$$\begin{aligned}
\sum_{1 \leq i < j \leq N} e_i e_j \chi(x_i) Y_{r^{-1}}(x_i - x_j)\chi(x_j) &\geq \tfrac{1}{2}\iint Y_{r^{-1}}(x - y)d\mu(x)d\mu(y) \\
&\quad -\tfrac{1}{2}\sum_{i=1}^{N}\chi(x_i)^2\iint Y_{r^{-1}}(x - y)d\mu_{D_i}(x)d\mu_{D_i}(y) \\
&\geq -\tfrac{1}{2}\sum_{i=1}^{N}\chi(x_i)^2\iint Y_{r^{-1}}(x - y)d\mu_{D_i}(x)d\mu_{D_i}(y)
\end{aligned}$$

since $Y_{r^{-1}}$ is positive type.

We calculate

$$\begin{aligned}
\iint Y_{r^{-1}}(x - y)d\mu_D(x)d\mu_D(y) &= \int W_D(x)d\mu_D(x) = \tfrac{1}{3}r^{-2}D^3 Y_{r^{-1}}(D)^2 - D^2 Y'_{r^{-1}}(D)Y_{r^{-1}}(D) \\
&= \tfrac{1}{3}\left(Dr^{-2} + 3D^{-1} + 3r^{-1}\right)e^{-2D/r}.
\end{aligned}$$

We have therefore proved the operator estimate

$$\sum_{i=1}^{N} -\frac{\delta}{2}\Delta_{i,\mathrm{Neu}} + \sum_{1 \le i < j \le N} e_i e_j \chi(x_i) Y_{r^{-1}}(x_i - x_j) \chi(x_j) \ge \sum_{i=1}^{N} -\frac{\delta}{2}\Delta_{i,\mathrm{Neu}} - v_i,$$

where for $i = 1, 2, \ldots, N$

$$v_i(x_i) = -\tfrac{1}{6}\chi(x_i)^2 \left(D_i r^{-2} + 3D_i^{-1} + 3r^{-1} \right) e^{-2D_i/r}.$$

Note that here D_i depends on x_i and the positions of all the particles with opposite charge of e_i.

From the Sobolev estimate for the Neumann Laplacian in a cube of size ℓ we have the general lower bound

$$-\Delta_{\mathrm{Neu}} - V \ge -C \int V^{5/2} - C\ell^{-3} \int V.$$

This gives for $e_i = \pm 1$ that

$$
\begin{aligned}
-\frac{\delta}{2}\Delta_{i,\mathrm{Neu}} - v_i \quad &\ge \quad -C\nu^{\mp} \int_{\mathbb{R}^3} \delta^{-3/2}\left(\frac{|x|}{r^2} + \frac{3}{|x|} + \frac{3}{r}\right)^{5/2} e^{-5|x|/r} + \ell^{-3}\left(\frac{|x|}{r^2} + \frac{3}{|x|} + \frac{3}{r}\right) e^{-2|x|/r}\, dx \\
&\ge \quad -C\nu^{\mp}(\delta^{-3/2}r^{1/2} + \ell^{-3}r^2).
\end{aligned}
$$

When summed over i this gives the result of the lemma. □

If we combine the bound (26) and Lemma 6.1 we have the following result.

6.2 LEMMA (Long and short distance potential cutoffs).
For $0 < \delta < \varepsilon < 1$ consider the Hamiltonian

$$\widetilde{H}_{r,R}^{\delta} \;=\; \sum_{i=1}^{N} \left(\frac{\gamma_{\varepsilon,t}}{2}\mathcal{K}_i^{(z)} - \frac{\gamma_{\varepsilon,t}}{2}(\varepsilon - \delta)\Delta_{i,\mathrm{Neu}}^{(z)} \right) + \sum_{1 \le i < j \le N} e_i e_j w_{r,R}(x_i, x_j) \tag{27}$$

where $w_{r,R}$ is given in (24) and (25). If $0 < r \le R < \omega(t)^{-1}\ell$ then the Hamiltonian $\widetilde{H}$ defined in (22) obeys the lower bound

$$\widetilde{H} \ge \widetilde{H}_{r,R}^{\delta} - \tfrac{1}{2}\nu R^{-1} - C\nu^{+}\nu^{-}(\delta^{-3/2}r^{1/2} + \ell^{-3}r^2). \tag{28}$$

If $0 < r \le R = \omega(t)^{-1}\ell$ we get

$$\widetilde{H} \ge \widetilde{H}_{r,R}^{\delta} - C\nu^{+}\nu^{-}(\delta^{-3/2}r^{1/2} + \ell^{-3}r^2). \tag{29}$$

A similar argument gives the following result.

6.3 LEMMA. *With the same notation as above we have for $0 < r \le r' \le R' \le R \le \omega(t)^{-1}\ell$ that*

$$\widetilde{H}_{r,R}^{\delta} \ge \widetilde{H}_{r',R'}^{2\delta} - \tfrac{1}{2}\nu R'^{-1} - C\nu^{+}\nu^{-}(\delta^{-3/2}r'^{1/2} + \ell^{-3}r'^2).$$

Proof. Simply note that $V_{r',R'}(x) - V_{r,R}(x) = Y_{R'^{-1}}(x) - Y_{R^{-1}}(x) + Y_{r^{-1}}(x) - Y_{r'^{-1}}(x)$ and now use the same arguments as before. □

We shall not fix the cutoffs r and R nor the parameter δ, but rather choose them differently at different stages in the later arguments. Moreover, we shall choose r and R to depend on ν. We give an example of this in the following corollary.

6.4 COROLLARY (Simple bound on the number of excited particles).

For any state such that the expectation $\langle \widetilde{H} \rangle \leq 0$, the expectation of the number of excited particles satisfies $\langle \nu - \widehat{n} \rangle \leq \nu \min\{1, C\varepsilon^{-1}\ell\nu^{1/3}\}$. (Recall that $\widetilde{H}$ depends on ε.)

Proof. We simply choose $r = R$ and $\delta = \varepsilon/2$ in Lemma 6.2. Then $\widetilde{H}^\delta_{r,R} \geq C(\varepsilon/2)(\nu - \widehat{n})\ell^{-2}$ since $(u, -\Delta^{(z)}_{\text{Neu}}u) \geq \pi^2\ell^{-2}\|u\|^2$ for functions u in the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$ orthogonal to constants. We therefore have that

$$\widetilde{H} \geq C(\varepsilon/2)(\nu - \widehat{n})\ell^{-2} - \tfrac{1}{2}\nu r^{-1} - C\nu^+\nu^-(\varepsilon^{-3/2}r^{1/2} + \ell^{-3}r^2).$$

Strictly speaking Lemma 6.2 requires $r \leq R \leq \omega(t)^{-1}\ell$. If however $R = r > \omega(t)^{-1}\ell$ we would get an even better estimate than the one stated if we set $r = R = \omega(t)^{-1}\ell$ and $\delta = \varepsilon/2$. Since in this case we may ignore the error $-\tfrac{1}{2}\nu r^{-1}$.

We now estimate $\nu^+\nu^- \leq \nu^2/4$ and make the explicit choice $r = \min\{\varepsilon\nu^{-2/3}, \ell\nu^{-1/3}\}$. When $\varepsilon\nu^{-2/3} \leq \ell\nu^{-1/3}$, i.e., $\nu^{1/3} \geq \varepsilon\ell^{-1}$ we obtain

$$\widetilde{H} \geq C(\varepsilon/2)(\nu - \widehat{n})\ell^{-2} - C\varepsilon^{-1}\nu^{5/3} - C\varepsilon^2\ell^{-3}\nu^{4/3} \geq C(\varepsilon/2)(\nu - \widehat{n})\ell^{-2} - C\varepsilon^{-1}\nu^{5/3}$$

and when $\varepsilon\nu^{-2/3} \geq \ell\nu^{-1/3}$, i.e., $\nu^{1/3} \leq \varepsilon\ell^{-1}$ we obtain

$$\widetilde{H} \geq C(\varepsilon/2)(\nu - \widehat{n})\ell^{-2} - C\varepsilon^{-3/2}\ell^{1/2}\nu^{11/6} - C\ell^{-1}\nu^{4/3} \geq C(\varepsilon/2)(\nu - \widehat{n})\ell^{-2} - C\ell^{-1}\nu^{4/3}.$$

These two bounds give that

$$\langle \nu - \widehat{n} \rangle \leq C\nu \max\{(\varepsilon^{-1}\ell\nu^{1/3})^2, \varepsilon^{-1}\ell\nu^{1/3}\}.$$

We of course clearly have that $\nu - \widehat{n} \leq \nu$. We therefore get the result claimed. $\square$

7   Bound on the unimportant part of the Hamiltonian

In this section we shall bound the Hamiltonian $\widetilde{H}^\delta_{r,R}$ given in (27). We emphasize that we do not necessarily have neutrality in the cube, i.e., ν^+ and ν^- may be different. We are simply looking for a lower bound to $\widetilde{H}^\delta_{r,R}$, that holds for all $\nu^\pm$. The goal is to find a lower bound that will allow us to conclude that the optimal value of $\nu^+ - \nu^-$, i.e., the value for which the energy of the Hamiltonian is smallest, is indeed close to zero. We shall also conclude that the number of excited particles $\nu - \widehat{n}$ is small. These conclusions will be made in Sects. 9 and 10.

In this section we shall fix $z = 0$, i.e., we are working in the cube $[-\ell/2, \ell/2]^3$. We shall simply omit the index z.

We shall express the Hamiltonian in second quantized language. This is purely for convenience. We stress that we are not in anyway changing the model by doing this and the treatment is entirely rigorous and could have been done without the use of second quantization.

Let u_p, $\ell p/\pi \in (\mathbb{N} \cup \{0\})^3$ be an orthonormal basis of eigenfunction of the Neumann Laplacian $-\Delta_{\text{Neu}}$ in the cube $[-\ell/2, \ell/2]^3$. More precisely, $-\Delta_{\text{Neu}} u_p = |p|^2 u_p$. I.e.,

$$u_p(x_1, x_2, x_3) = c_p \ell^{-3/2} \prod_{j=1}^{3} \cos\left(\frac{p_j \pi (x_j + \ell/2)}{\ell}\right),$$

where the normalization satisfies $c_0 = 1$ and in general $1 \leq c_p \leq \sqrt{8}$. The function $u_0 = \ell^{-3/2}$ is the constant eigenfunction with eigenvalue 0. We note that for $p \neq 0$ we have

$$(u_p, -\Delta_{\text{Neu}} u_p) \geq \pi^2 \ell^{-2}. \tag{30}$$

We now express the Hamiltonian $\widetilde{H}_{r,R}^\delta$ from (27) (omitting z) in terms of the creation and annihilation operators $a_{p\pm}^* = a_\pm(u_p)^*$ and $a_{p\pm} = a_\pm(u_p)$.

Define

$$\widehat{w}_{pq,\mu\nu} = \iint w_{r,R}(x, y) u_p(x) u_q(y) u_\mu(x) u_\nu(y) \, dx \, dy.$$

We may then express the two-body potential in $\widetilde{H}_{r,R}^\delta$ as

$$\sum_{1 \leq i < j \leq n} e_i e_j w_{r,R}(x_i, x_j) = \tfrac{1}{2} \sum_{pq,\mu\nu} \widehat{w}_{pq,\mu\nu} \left(a_{p+}^* a_{q+}^* a_{\nu+} a_{\mu+} + a_{p-}^* a_{q-}^* a_{\nu-} a_{\mu-} - 2a_{p+}^* a_{q-}^* a_{\nu-} a_{\mu+}\right).$$

Motivated by Foldy's and Dyson's use of the Bogolubov approximation it is our goal to reduce the Hamiltonian $\widetilde{H}_{r,R}^\delta$ so that it has only what we call quadratic terms, i.e., terms which contain precisely two $a_{p\pm}^\#$ with $p \neq 0$. More precisely, we want to be able to ignore all terms in the two-body-potential containing the coefficients

- $\widehat{w}_{00,00}$.

- $\widehat{w}_{p0,q0} = \widehat{w}_{0p,0q}$, where $p, q \neq 0$. These terms are in fact quadratic, but do not appear in the Foldy Hamiltonian. We shall prove that they can also be ignored.

- $\widehat{w}_{p0,00} = \widehat{w}_{0p,00} = \widehat{w}_{00,p0} = \widehat{w}_{00,0p}$, where $p \neq 0$.

- $\widehat{w}_{pq,\mu0} = \widehat{w}_{\mu0,pq} = \widehat{w}_{qp,0\mu} = \widehat{w}_{0\mu,qp}$, where $p, q, \mu \neq 0$.

- $\widehat{w}_{pq,\mu\nu}$, where $p, q, \mu, \nu \neq 0$.

We shall consider these cases one at a time.

7.1 LEMMA (Control of terms with $\widehat{w}_{00,00}$).

The sum of the terms in $\widetilde{H}_{r,R}^\delta$ containing $\widehat{w}_{00,00}$ is equal to

$$\tfrac{1}{2} \widehat{w}_{00,00} \left[(\widehat{n}^+ - \widehat{n}^-)^2 - \widehat{n}^+ - \widehat{n}^-\right].$$

Proof. The terms containing $\widehat{w}_{00,00}$ are

$$\tfrac{1}{2}\widehat{w}_{00,00}\left(a_{0+}^*a_{0+}^*a_{0+}a_{0+} + a_{0-}^*a_{0-}^*a_{0-}a_{0-} - 2a_{0+}^*a_{0-}^*a_{0-}a_{0+}\right),$$

which gives the above result when using the commutation relation $[a_p, a_q^*] = \delta_{p,q}$. $\square$

7.2 LEMMA (Control of terms with $\widehat{w}_{p0,q0}$).
The sum of the terms in $\widetilde{H}_{r,R}^\delta$ containing $\widehat{w}_{p0,q0}$ or $\widehat{w}_{0p,0q}$ with $p, q \neq 0$ is bounded below by

$$-4\pi R^2 \ell^{-3}|\widehat{n}^+ - \widehat{n}^-|(\nu - \widehat{n}).$$

Proof. The terms containing $\widehat{w}_{p0,q0} = \widehat{w}_{0p,0q}$ are

$$\sum_{\substack{p\neq 0\\q\neq 0}} \widehat{w}_{p0,q0}\left(a_{p+}^*a_{0+}^*a_{0+}a_{q+} + a_{p-}^*a_{0-}^*a_{0-}a_{q-} - a_{p+}^*a_{0-}^*a_{0-}a_{q+} - a_{p-}^*a_{0+}^*a_{0+}a_{q-}\right)$$

$$= \sum_{\substack{p\neq 0\\q\neq 0}} \widehat{w}_{p0,q0}(\widehat{n}^+ - \widehat{n}^-)(a_{p+}^*a_{q+} - a_{p-}^*a_{q-}).$$

Note that $\widehat{n}^{\pm}$ commutes with $\sum_{\substack{p\neq 0\\q\neq 0}} \widehat{w}_{p0,q0}a_{p\pm}^*a_{q\pm}$.

We have that

$$\widehat{w}_{p0,q0} = \ell^{-3}\int\int w_{r,R}(x, y)\,dy\,u_p(x)u_q(x)\,dx.$$

Hence

$$\sum_{\substack{p\neq 0\\q\neq 0}} \widehat{w}_{p0,q0}a_{p\pm}^*a_{q\pm} = \ell^{-3}\int\int w_{r,R}(x, y)\,dy\left(\sum_{p\neq 0}u_p(x)a_{p\pm}^*\right)\left(\sum_{p\neq 0}u_p(x)a_{p\pm}^*\right)^*dx.$$

$$\leq \ell^{-3}\sup_{x'}\int w_{r,R}(x', y)\,dy\int\left(\sum_{p\neq 0}u_p(x)a_{p\pm}^*\right)\left(\sum_{p\neq 0}u_p(x)a_{p\pm}^*\right)^*dx.$$

$$= \ell^{-3}\sup_{x'}\int w_{r,R}(x', y)\,dy\sum_{p\neq 0}a_{p\pm}^*a_{p\pm}.$$

Since $\sum_{p\neq 0}a_{p\pm}^*a_{p\pm} = \nu^{\pm} - \widehat{n}^{\pm}$ and

$$\sup_x\int w_{r,R}(x, y)\,dy \leq \int V_{r,R}(y)\,dy \leq 4\pi R^2$$

we obtain the operator inequality

$$0 \leq \sum_{\substack{p\neq 0\\q\neq 0}} \widehat{w}_{p0,q0}a_{p\pm}^*a_{q\pm} \leq 4\pi\ell^{-3}R^2(\nu^{\pm} - \widehat{n}^{\pm}),$$

and the lemma follows. $\square$

Before treating the last three types of terms we shall need the following result on the structure of the coefficients $\widehat{w}_{pq,\mu\nu}$.

7.3 LEMMA. *For all $p', q' \in (\pi/\ell)(\mathbb{N} \cup \{0\})^3$ and $\alpha \in \mathbb{N}$ there exists $J^\alpha_{p'q'} \in \mathbb{R}$ with $J^\alpha_{p'q'} = J^\alpha_{q'p'}$ such that for all $p, q, \mu, \nu \in (\pi/\ell)(\mathbb{N} \cup \{0\})^3$ we have*

$$\widehat{w}_{pq,\mu\nu} = \sum_\alpha J^\alpha_{p\mu} J^\alpha_{q\nu}. \tag{31}$$

Moreover we have the operator inequalities

$$0 \le \sum_{p,p' \ne 0} \widehat{w}_{pp',00} a^*_{p\pm} a_{p'\pm} = \sum_{p,p' \ne 0} \widehat{w}_{p0,0p'} a^*_{p\pm} a_{p'\pm} \le 4\pi\ell^{-3} R^2 (\nu^\pm - \widehat{n}^\pm) \tag{32}$$

and

$$0 \le \sum_{p,p',m \ne 0} \widehat{w}_{pm,mp'} a^*_{p\pm} a_{p'\pm} \le r^{-1}(\nu^\pm - \widehat{n}^\pm).$$

Proof. The operator $\mathcal{A}$ with integral kernel $w_{r,R}(x,y)$ is a non-negative Hilbert-Schmidt operator on $L^2(\mathbb{R}^3)$ with norm less than $\sup_k \hat{V}_{r,R}(k) \le 4\pi R^2$. Denote the eigenvalues of $\mathcal{A}$ by λ_α, $\alpha = 1, 2, \ldots$ and corresponding orthonormal eigenfunctions by φ_α. We may assume that these functions are real. The eigenvalues satisfy $0 \le \lambda_\alpha \le 4\pi R^2$. We then have

$$\widehat{w}_{pq,\mu\nu} = \sum_\alpha \lambda_\alpha \int u_p(x) u_\mu(x) \varphi_\alpha(x)\, dx \int u_q(y) u_\nu(y) \varphi_\alpha(y)\, dy.$$

The identity (31) thus follows with $J^\alpha_{p\mu} = \lambda_\alpha^{1/2} \int u_p(x) u_\mu(x) \varphi_\alpha(x)\, dx$.

If as before $\mathcal{P}$ denotes the projection orthogonal to constants we may also consider the operator $\mathcal{PAP}$. Denote its eigenvalues and eigenfunctions by λ'_α and φ'_α. Then again $0 \le \lambda'_\alpha \le 4\pi R^2$. Hence we may write

$$\widehat{w}_{p0,0p'} = \ell^{-3} \sum_\alpha \lambda'_\alpha \int u_p(x) \varphi'_\alpha(x)\, dx \int u_{p'}(y) \varphi'_\alpha(y)\, dy.$$

Thus since all φ'_α are orthogonal to constants we have

$$\sum_{p,p' \ne 0} \widehat{w}_{p0,0p'} a^*_{p\pm} a_{p'\pm}$$

$$= \ell^{-3} \sum_\alpha \lambda'_\alpha \left(\sum_{p \ne 0} \int u_p(x) \varphi'_\alpha(x)\, dx\, a^*_{p\pm} \right) \left(\sum_{p \ne 0} \int u_p(x) \varphi'_\alpha(x)\, dx\, a^*_{p\pm} \right)^*$$

$$= \ell^{-3} \sum_\alpha \lambda'_\alpha a^*_\pm (\varphi'_\alpha) a_\pm (\varphi'_\alpha).$$

The inequalities (32) follow immediately from this.

The fact that $\sum_{p,p',m \ne 0} \widehat{w}_{pm,mp'} a^*_{p\pm} a_{p'\pm} \ge 0$ follows from the representation (31). Moreover, since the kernel $w_{r,R}(x,y)$ is a continuous function we have that $w_{r,R}(x,x) = \sum_\alpha \lambda_\alpha \varphi_\alpha(x)^2$ for almost all x and hence

$$\sum_{m \ne 0} \widehat{w}_{pm,mp'} = \int u_p(x) u_{p'}(x) w_{r,R}(x,x)\, dx - \widehat{w}_{p0,0p'}.$$

We therefore have

$$\sum_{p,p',m\neq 0} \widehat{w}_{pm,mp'} a_{p\pm}^* a_{p'\pm} \leq \sum_{p,p'\neq 0} \int u_p(x) u_{p'}(x) w_{r,R}(x,x)\, dx\, a_{p\pm}^* a_{p'\pm}$$

$$= \int w_{r,R}(x,x) \left(\sum_{p\neq 0} u_p(x) a_{p\pm}^*\right)\left(\sum_{p\neq 0} u_p(x) a_{p\pm}^*\right)^* dx$$

$$\leq \sup_{x'} w_{r,R}(x',x') \int \left(\sum_{p\neq 0} u_p(x) a_{p\pm}^*\right)\left(\sum_{p\neq 0} u_p(x) a_{p\pm}^*\right)^* dx = \sup_{x'} w_{r,R}(x',x')(\nu^\pm - \widehat{n}^\pm)$$

and the lemma follows since $\sup_{x'} w_{r,R}(x',x') \leq r^{-1}$. $\qquad\qquad\square$

7.4 LEMMA (Control of terms with $\widehat{w}_{pq,\mu\nu}$).

The sum of the terms in $\widetilde{H}_{r,R}^\delta$ containing $\widehat{w}_{pq,\mu\nu}$, with $p,q,\mu,\nu \neq 0$ is bounded below by

$$\frac{1}{2}\sum_\alpha \left(\sum_{p\mu\neq 0} J_{p\mu}^\alpha (a_{p+}^* a_{\mu+} - a_{p-}^* a_{\mu-})\right)^2 - \frac{1}{2} r^{-1}(\nu - \widehat{n}).$$

Proof. The relevant terms are

$$\frac{1}{2}\sum_{pq,\mu\nu\neq 0} \widehat{w}_{pq,\mu\nu}\left(a_{p+}^* a_{q+}^* a_{\nu+} a_{\mu+} + a_{p-}^* a_{q-}^* a_{\nu-} a_{\mu-} - 2a_{p+}^* a_{q-}^* a_{\nu-} a_{\mu+}\right)$$

$$= \frac{1}{2}\sum_{pq,\mu\nu\neq 0} \widehat{w}_{pq,\mu\nu}\left(a_{p+}^* a_{\mu+} a_{q+}^* a_{\nu+} + a_{p-}^* a_{\mu-} a_{q-}^* a_{\nu-} - 2a_{p+}^* a_{q-}^* a_{\nu-} a_{\mu+}\right)$$

$$- \frac{1}{2}\sum_{pp',m\neq 0} \widehat{w}_{pm,mp'} a_{p+}^* a_{p'+} - \frac{1}{2}\sum_{pp',m\neq 0} \widehat{w}_{pm,mp'} a_{p-}^* a_{p'-}$$

$$= \frac{1}{2}\sum_\alpha \left(\sum_{p\mu\neq 0} J_{p\mu}^\alpha (a_{p+}^* a_{\mu+} - a_{p-}^* a_{\mu-})\right)^2 - \frac{1}{2} r^{-1}(\nu - \widehat{n}),$$

where we have used the last estimate in Lemma 7.3 and that $\nu^+ - \widehat{n}^+ + \nu^- - \widehat{n}^- = \nu - \widehat{n}$. $\qquad\square$

7.5 LEMMA (Control of terms with $\widehat{w}_{p0,00}$).

The sum of the terms in $\widetilde{H}_{r,R}^\delta$ containing $\widehat{w}_{p0,00}$, $\widehat{w}_{0p,00}$, $\widehat{w}_{00,p0}$, or $\widehat{w}_{00,0p}$, with $p \neq 0$ is, for all $\varepsilon' > 0$, bounded below by

$$-\varepsilon'^{-1} 4\pi \ell^{-3} R^2 (\widehat{n}+1)(\nu - \widehat{n}) - 2\varepsilon' \widehat{w}_{00,00}\left((\widehat{n}^+ - \widehat{n}^-)^2 + 1\right), \tag{33}$$

or by

$$(\nu^+ - \nu^-)\sum_{p\neq 0} \widehat{w}_{p0,00}\left(a_{p+}^* a_{0+} - a_{p-}^* a_{0-} + a_{0+}^* a_{p+} - a_{0-}^* a_{p-}\right)$$

$$-\varepsilon'^{-1} 4\pi \ell^{-3} R^2 (\widehat{n}+1)(\nu - \widehat{n}) - 2\varepsilon' \widehat{w}_{00,00}\left((\nu - \widehat{n})^2 + 1\right)). \tag{34}$$

Proof. The terms containing $\widehat{w}_{p0,00}$, $\widehat{w}_{0p,00}$, $\widehat{w}_{00,p0}$, or $\widehat{w}_{00,0p}$ are

$$\sum_{p\neq 0} \tfrac{1}{2}\widehat{w}_{p0,00} \Big(2a^*_{p+}a^*_{0+}a_{0+}a_{0+} + 2a^*_{0+}a^*_{0+}a_{0+}a_{p+} + 2a^*_{p-}a^*_{0-}a_{0-}a_{0-} + 2a^*_{0-}a^*_{0-}a_{0-}a_{p-}$$

$$-2a^*_{0-}a_{0-}a^*_{0+}a_{p+} - 2a^*_{0-}a_{0-}a^*_{p+}a_{0+} - 2a^*_{0+}a_{0+}a^*_{0-}a_{p-} - 2a^*_{0+}a_{0+}a^*_{p-}a_{0-} \Big)$$

$$= \sum_{\alpha}\sum_{p\neq 0} J^\alpha_{p0} J^\alpha_{00} \left((\widehat{n}^+ - \widehat{n}^-)(a^*_{p+}a_{0+} - a^*_{p-}a_{0-}) + (a^*_{0+}a_{p+} - a^*_{0-}a_{p-})(\widehat{n}^+ - \widehat{n}^-) \right)$$

$$= \sum_{\alpha}\sum_{p\neq 0} J^\alpha_{p0} J^\alpha_{00} \left(a^*_{p+}a_{0+}(\widehat{n}^+ + 1 - \widehat{n}^-) + (\widehat{n}^+ + 1 - \widehat{n}^-)a^*_{0+}a_{p+} \right)$$

$$- \sum_{\alpha}\sum_{p\neq 0} J^\alpha_{p0} J^\alpha_{00} \left(a^*_{p-}a_{0-}(\widehat{n}^+ - \widehat{n}^- - 1) + a^*_{0-}a_{p-}(\widehat{n}^+ - \widehat{n}^- - 1) \right)$$

$$\geq -\varepsilon' \sum_{\alpha} (J^\alpha_{00})^2 \left((\widehat{n}^+ - \widehat{n}^- + 1)^2 + (\widehat{n}^+ - \widehat{n}^- - 1)^2 \right)$$

$$-\varepsilon'^{-1}(\widehat{n}^+ + 1) \sum_{\alpha}\sum_{p,p'\neq 0} J^\alpha_{p0} J^\alpha_{p'0} a^*_{p+}a_{p'+} - \varepsilon'^{-1}(\widehat{n}^- + 1) \sum_{\alpha}\sum_{p,p'\neq 0} J^\alpha_{p0} J^\alpha_{p'0} a^*_{p-}a_{p'-}.$$

Here we have used the representation (31) and in the last step a Cauchy-Schwarz inequality. We arrive at the first bound in the lemma since from (32) we have that

$$\sum_{\alpha}\sum_{p,p'\neq 0} J^\alpha_{p0} J^\alpha_{p'0} a^*_{p\pm}a_{p'\pm} = \sum_{p,p'\neq 0} \widehat{w}_{p0,0p'} a^*_{p\pm}a_{p'\pm} \leq 4\pi\ell^{-3}R^2(\nu^\pm - \widehat{n}^\pm).$$

The second bound (34) follows in the same way if we notice that the terms containing $\widehat{w}_{p0,00}$, $\widehat{w}_{0p,00}$, $\widehat{w}_{00,p0}$, or $\widehat{w}_{00,0p}$ may be written as

$$(\nu^+ - \nu^-) \sum_{p\neq 0} \widehat{w}_{p0,00} \left(a^*_{p+}a_{0+} - a^*_{p-}a_{0-} + a^*_{0+}a_{p+} - a^*_{0-}a_{p-} \right)$$

$$+ \sum_{\alpha}\sum_{p\neq 0} J^\alpha_{p0} J^\alpha_{00} \Big((\widehat{n}^+ - \nu^+ - \widehat{n}^- + \nu^-)(a^*_{p+}a_{0+} - a^*_{p-}a_{0-})$$

$$+ (a^*_{0+}a_{p+} - a^*_{0-}a_{p-})(\widehat{n}^+ - \nu^+ - \widehat{n}^- + \nu^-) \Big).$$

$\square$

7.6 LEMMA (Control of terms with $\widehat{w}_{pq,m0}$).

The sum of the terms in $\widetilde{H}^\delta_{r,R}$ containing $\widehat{w}_{pq,m0}$, $\widehat{w}_{qp,0m}$, $\widehat{w}_{m0,pq}$, or $\widehat{w}_{0m,qp}$, with $p,q,m \neq 0$ is bounded below by

$$-\varepsilon'^{-1}4\pi\ell^{-3}R^2(\widehat{n} + 1)(\nu - \widehat{n}) - 2\varepsilon' \sum_{\alpha}\left(\sum_{p\mu\neq 0} J^\alpha_{p\mu}(a^*_{p+}a_{\mu+} - a^*_{p-}a_{\mu-}) \right)^2,$$

for all $\varepsilon' > 0$.

Proof. The terms containing $\widehat{w}_{pq,m0}$, $\widehat{w}_{qp,0m}$, $\widehat{w}_{m0,pq}$, or $\widehat{w}_{0m,qp}$, with $p,q,m \neq 0$ are

$$\sum_{pqm\neq 0} \widehat{w}_{pq,m0} \Big(a^*_{p+}a^*_{q+}a_{m+}a_{0+} + a^*_{0+}a^*_{m+}a_{q+}a_{p+} + a^*_{p-}a^*_{q-}a_{m-}a_{0-} + a^*_{0-}a^*_{m-}a_{q-}a_{p-}$$

$$-a_{p+}^* a_{q-}^* a_{m+} a_{0-} - a_{0-}^* a_{m+}^* a_{q-} a_{p+} - a_{p-}^* a_{q+}^* a_{m-} a_{0+} - a_{0+}^* a_{m-}^* a_{q+} a_{p-}\Big)$$

$$= \sum_{\alpha} \sum_{q \neq 0} J_{q0}^\alpha (a_{q+}^* a_{0+} - a_{q-}^* a_{0-}) \sum_{pm \neq 0} J_{pm}^\alpha (a_{p+}^* a_{m+} - a_{p-}^* a_{m-})$$

$$+ \sum_{\alpha} \sum_{pm \neq 0} J_{pm}^\alpha (a_{p+}^* a_{m+} - a_{p-}^* a_{m-}) \sum_{q \neq 0} J_{q0}^\alpha (a_{q+}^* a_{0+} - a_{q-}^* a_{0-})^*$$

$$\geq -\varepsilon'^{-1} \sum_{qq' \neq 0} \widehat{w}_{q0,0q'} a_{q+}^* a_{q'+} a_{0+} a_{0+}^* - \varepsilon'^{-1} \sum_{qq' \neq 0} \widehat{w}_{q0,0q'} a_{q-}^* a_{q'-} a_{0-} a_{0-}^*$$

$$-2\varepsilon' \sum_{\alpha} \Big(\sum_{pm \neq 0} J_{pm}^\alpha (a_{p+}^* a_{m+} - a_{p-}^* a_{m-}) \Big)^2$$

The lemma follows from (32). $\qquad\qquad \square$

Note that if $\varepsilon' \leq 1/4$ then the last term in the estimate in Lemma 7.6 can be controlled by the positive term in Lemma 7.4.

8 Analyzing the quadratic Hamiltonian

In this section we consider the main part of the Hamiltonian $\widetilde{H}_{r,R}^\delta$, namely the "quadratic" Hamiltonian considered by Foldy. As in the previous section we have fixed $z = 0$, i.e., we consider the cube $[-\ell/2, \ell/2]^3$ and we omit z. The "quadratic" Hamiltonian consists of the kinetic energy $\mathcal{K}$ from (13) and all the two-body terms with the coefficients $\widehat{w}_{pq,00}$, $\widehat{w}_{00,pq}$ $\widehat{w}_{p0,0q}$, and $\widehat{w}_{0p,q0}$ with $p, q \neq 0$, i.e.,

$$H_{\text{Foldy}} = \sum_{i=1}^N \frac{\gamma_{\varepsilon,t}}{2} \mathcal{K}_i + \tfrac{1}{2} \sum_{pq \neq 0} \widehat{w}_{pq,00} \Big(2a_{p+}^* a_{0+}^* a_{0+} a_{q+} + a_{p+}^* a_{q+}^* a_{0+} a_{0+} + a_{0+}^* a_{0+}^* a_{p+} a_{q+}$$

$$+ 2a_{p-}^* a_{0-}^* a_{0-} a_{q-} + a_{p-}^* a_{q-}^* a_{0-} a_{0-} + a_{0-}^* a_{0-}^* a_{p-} a_{q-}$$

$$- 2a_{p+}^* a_{q-}^* a_{0-} a_{0+} - 2a_{0+}^* a_{0-}^* a_{q-} a_{p+}$$

$$- 2a_{p+}^* a_{0-}^* a_{q-} a_{0+} - 2a_{0+}^* a_{q-}^* a_{0-} a_{p+} \Big). \qquad (35)$$

In order to compute all the bounds we found it necessary to include the first term in (34) into the "quadratic" Hamiltonian. We therefore define

$$H_Q = H_{\text{Foldy}} + (\nu^+ - \nu^-) \sum_{p \neq 0} \widehat{w}_{p0,00} \left(a_{p+}^* a_{0+} - a_{p-}^* a_{0-} + a_{0+}^* a_{p+} - a_{0-}^* a_{p-} \right). \qquad (36)$$

Our goal is to give a lower bound on the ground state energy of the Hamiltonian H_Q.

For any $k \in \mathbb{R}^3$ denote $\chi_k(x) = e^{ikx}\chi(x)$ and define the operators

$$b_{k\pm}^* = (\ell^3 \nu^\pm)^{-1/2} a_\pm^* (\mathcal{P}\chi_k) a_{0\pm} \quad \text{and} \quad b_{k\pm} = (\ell^3 \nu^\pm)^{-1/2} a_\pm (\mathcal{P}\chi_k) a_{0\pm}^*,$$

where as before $\mathcal{P}$ denotes the projection orthogonal to constants. (On the subspace where $\nu^+ = 0$ we set $b_{k+}^* = 0$ and likewise when $\nu^- = 0$ we set $b_{k-}^* = 0$.) These operators satisfy the commutation relations (note that $a_{0\pm}$ commutes with $a_\pm^*(\mathcal{P}\chi_k)$)

$$[b_{k+}, b_{k'-}^*] = [b_{k+}^*, b_{k'-}^*] = [b_{k-}^*, b_{k'-}^*] = 0 \qquad (37)$$

and[1]

$$[b_{k\pm}, b_{k'\pm}^*] = (\ell^3 \nu^\pm)^{-1} a_{0\pm}^* a_{0\pm} (\mathcal{P}\chi_k, \mathcal{P}\chi_{k'}) - (\ell^3 \nu^\pm)^{-1} a_\pm^*(\mathcal{P}\chi_{k'}) a_\pm(\mathcal{P}\chi_k).$$

In particular, we get

$$[b_{k\pm}, b_{k\pm}^*] \leq (\ell^3 \nu^\pm)^{-1} a_{0\pm}^* a_{0\pm} (\mathcal{P}\chi_k, \mathcal{P}\chi_k) \leq 1. \tag{38}$$

We shall now estimate the "quadratic" Hamiltonian below by an operator that is really quadratic in the operators $b_{k\pm}^*$ and $b_{k\pm}$.

8.1 LEMMA (The quadratic Hamiltonian).

The quadratic Hamiltonian satisfies the lower bound

$$H_Q \geq \int_{\mathbb{R}^3} h_Q(k)\, dk - \sum_{pq \neq 0} \widehat{w}_{pq,00}(a_{p+}^* a_{q+} + a_{p-}^* a_{q-}), \tag{39}$$

where

$$
\begin{aligned}
h_Q(k) &= (2\pi)^{-3} \frac{\ell^3 \gamma_{\varepsilon,t}}{4} \frac{|k|^4}{|k|^2 + (\ell t^6)^{-2}} \left(b_{k+}^* b_{k+} + b_{-k+}^* b_{-k+} + b_{k-}^* b_{k-} + b_{-k-}^* b_{-k-} \right) \\
&\quad + \frac{\hat{V}_{r,R}(k)}{2(2\pi)^3} \Big[(\nu^+ - \nu^-)\ell^{-3} \Big(\widehat{\chi}(k)(\nu^+)^{1/2} b_{k+}^* + (\nu^+)^{1/2} b_{-k+} - (\nu^-)^{1/2} b_{k-}^* - (\nu^-)^{1/2} b_{-k-} \Big) \\
&\quad\quad + \overline{\widehat{\chi}(k)}\big((\nu^+)^{1/2} b_{k+} + (\nu^+)^{1/2} b_{-k+}^* - (\nu^-)^{1/2} b_{k-} - (\nu^-)^{1/2} b_{-k-}^* \big) \Big) \\
&\quad + \nu^+ (b_{k+}^* b_{k+} + b_{-k+}^* b_{-k+} + b_{k+}^* b_{-k+}^* + b_{k+} b_{-k+}) \\
&\quad + \nu^- (b_{k-}^* b_{k-} + b_{-k-}^* b_{-k-} + b_{k-}^* b_{-k-}^* + b_{k-} b_{-k-}) \\
&\quad - (\nu^- \nu^+)^{1/2} (b_{k+}^* b_{k-} + b_{-k+}^* b_{-k-} + b_{k-}^* b_{k+} + b_{-k-}^* b_{-k+}) \\
&\quad - (\nu^- \nu^+)^{1/2} (b_{k+}^* b_{-k-}^* + b_{-k+}^* b_{k-}^* + b_{k+} b_{-k-} + b_{-k+} b_{k-}) \Big]. \tag{40}
\end{aligned}
$$

Proof. We consider first the kinetic energy

$$
\begin{aligned}
\frac{\gamma_{\varepsilon,t}}{2} \sum_{i=1}^N \mathcal{K}_i &= \frac{\gamma_{\varepsilon,t}}{2} \sum_{p,q} (a_{p+}^* a_{q+} + a_{p-}^* a_{q-})(u_p, \mathcal{K} u_q) \\
&= (2\pi)^{-3} \frac{\gamma_{\varepsilon,t}}{2} \int \frac{|k|^4}{|k|^2 + (\ell t^6)^{-2}} \sum_{p,q \neq 0} (a_{p+}^* a_{q+} + a_{p-}^* a_{q-})(u_p, \chi_k)(\chi_k, u_q)\, dk \\
&= (2\pi)^{-3} \frac{\gamma_{\varepsilon,t}}{2} \int \frac{|k|^4}{|k|^2 + (\ell t^6)^{-2}} (a_+^*(\mathcal{P}\chi_k) a_+(\mathcal{P}\chi_k) + a_-^*(\mathcal{P}\chi_k) a_-(\mathcal{P}\chi_k))\, dk.
\end{aligned}
$$

We get the first line in the expression for $h_Q(k)$ if we use that

$$a_\pm^*(\mathcal{P}\chi_k) a_\pm(\mathcal{P}\chi_k) \geq (\nu^\pm)^{-1} a_\pm^*(\mathcal{P}\chi_k) a_{0\pm} a_{0\pm}^* a_\pm(\mathcal{P}\chi_k) = \ell^3 b_{k\pm}^* b_{k\pm}.$$

---

[1] The corresponding equation (25) in [LSo] has a typographical error.

Since

$$w_{r,R}(x,y) = (2\pi)^{-3} \int \hat{V}_{r,R}(k)\chi_k(x)\overline{\chi_k(y)}\, dk,$$

we have that

$$\hat{w}_{pq,00} = (2\pi\ell)^{-3} \int \hat{V}_{r,R}(k)(u_p,\mathcal{P}\chi_k)(\mathcal{P}\chi_k,u_q)\, dk = (2\pi\ell)^{-3} \int \hat{V}_{r,R}(k)(u_p,\mathcal{P}\chi_k)(u_q,\mathcal{P}\chi_{-k})\, dk.$$

If we use that $\hat{V}_{r,R}(k) = \hat{V}_{r,R}(-k)$ and $\overline{\hat{\chi}(k)} = \hat{\chi}(-k)$ we arrive at the expression for h_Q. The last sum in (39) comes from commuting $a_{0\pm}^* a_{0\pm}$ to $a_{0\pm} a_{0\pm}^*$. $\square$

8.2 THEOREM (Particular case of Bogolubov's method).

For arbitrary constants $\mathcal{A}, \mathcal{B}_+, \mathcal{B}_- > 0$ and $\kappa \in \mathbb{C}$ we have for each fixed $k \in \mathbb{R}^3$ the inequality

$$\begin{aligned}
\mathcal{A}(b_{k+}^* b_{k+} &+ b_{-k+}^* b_{-k+} + b_{k-}^* b_{k-} + b_{-k-}^* b_{-k-}) \\
&+\kappa\left(\mathcal{B}_+^{1/2} b_{k+}^* - \mathcal{B}_-^{1/2} b_{k-}^* + \mathcal{B}_+^{1/2} b_{-k+} - \mathcal{B}_-^{1/2} b_{-k-}\right) \\
&+\overline{\kappa}\left(\mathcal{B}_+^{1/2} b_{k+} - \mathcal{B}_-^{1/2} b_{k-} + \mathcal{B}_+^{1/2} b_{-k+}^* - \mathcal{B}_-^{1/2} b_{-k-}^*\right) \\
&+\mathcal{B}_+\left(b_{k+}^* b_{k+} + b_{-k+}^* b_{-k+} + b_{k+}^* b_{-k+}^* + b_{k+} b_{-k+}\right) \\
&+\mathcal{B}_-\left(b_{k-}^* b_{k-} + b_{-k-}^* b_{-k-} + b_{k-}^* b_{-k-}^* + b_{k-} b_{-k-}\right) \\
&-(\mathcal{B}_+\mathcal{B}_-)^{1/2}\Big(b_{k+}^* b_{k-} + b_{-k+}^* b_{-k-} + b_{k-}^* b_{k+} + b_{-k-}^* b_{-k+} \\
&\qquad\qquad\qquad + b_{k+}^* b_{-k-}^* + b_{-k+}^* b_{k-}^* + b_{k+} b_{-k-} + b_{-k+} b_{k-}\Big) \\
\geq\quad &-(\mathcal{A}+\mathcal{B}_+ + \mathcal{B}_-) + \sqrt{(\mathcal{A}+\mathcal{B}_++\mathcal{B}_-)^2 - (\mathcal{B}_++\mathcal{B}_-)^2} - |\kappa|^2. \qquad (41)
\end{aligned}$$

Proof. Let us introduce

$$d_\pm^* = (\mathcal{B}_+ + \mathcal{B}_-)^{-1/2}(\mathcal{B}_+^{1/2} b_{\pm k+}^* - \mathcal{B}_-^{1/2} b_{\pm k-}^*), \quad c_\pm^* = (\mathcal{B}_+ + \mathcal{B}_-)^{-1/2}(\mathcal{B}_-^{1/2} b_{\pm k+}^* + \mathcal{B}_+^{1/2} b_{\pm k-}^*).$$

According to (37) and (38) these operators satisfy

$$[d_+^*, d_-^*] = 0, \quad [c_+^*, c_-^*] = 0, \quad [d_+, d_+^*] \leq 1, \quad [d_-, d_-^*] \leq 1, \quad [c_+, c_+^*] \leq 1, \quad [c_-, c_-^*] \leq 1.$$

The right side of (41) can be rewritten as

$$\begin{aligned}
\mathcal{A}(d_+^* d_+ &+ d_-^* d_- + c_+^* c_+ + c_-^* c_-) \\
&+(\mathcal{B}_+ + \mathcal{B}_-)\left(d_+^* d_+ + d_-^* d_- + d_+^* d_-^* + d_+ d_- + (\mathcal{B}_+ + \mathcal{B}_-)^{-1/2}\left(\kappa(d_+^* + d_-) + \overline{\kappa}(d_+ + d_-^*)\right)\right).
\end{aligned}$$

We may now complete the squares to write this as

$$\begin{aligned}
\mathcal{A}(c_+^* c_+ &+ c_-^* c_-) + D(d_+^* + \alpha d_- + a)(d_+^* + \alpha d_- + a)^* + D(d_-^* + \alpha d_+ + \overline{a})(d_-^* + \alpha d_+ + \overline{a})^* \\
&-D\alpha^2([d_+, d_+^*] + [d_-, d_-^*]) - 2D|a|^2
\end{aligned}$$

if

$$D(1 + \alpha^2) = \mathcal{A} + \mathcal{B}_+ + \mathcal{B}_-, \quad 2D\alpha = \mathcal{B}_+ + \mathcal{B}_-, \quad aD(1 + \alpha) = \kappa(\mathcal{B}_+ + \mathcal{B}_-)^{1/2}.$$

We choose the solution $\alpha = 1 + \frac{\mathcal{A}}{\mathcal{B}_+ + \mathcal{B}_-} - \sqrt{\left(1 + \frac{\mathcal{A}}{(\mathcal{B}_+ + \mathcal{B}_-)}\right)^2 - 1}$. Hence

$$D\alpha^2 = (\mathcal{B}_+ + \mathcal{B}_-)\alpha/2 = \tfrac{1}{2}\left(\mathcal{A} + \mathcal{B}_+ + \mathcal{B}_- - \sqrt{(\mathcal{A} + \mathcal{B}_+ + \mathcal{B}_-)^2 - (\mathcal{B}_+ + \mathcal{B}_-)^2}\right),$$

$$D|a|^2 = \frac{|\kappa|^2(\mathcal{B}_+ + \mathcal{B}_-)}{D(1 + \alpha^2 + 2\alpha)} = \frac{|\kappa|^2(\mathcal{B}_+ + \mathcal{B}_-)}{\mathcal{A} + 2\mathcal{B}_+ + 2\mathcal{B}_-} \leq \tfrac{1}{2}|\kappa|^2.$$

$\square$

Usually when applying Bogolubov's method the operators b and b^* satisfy the canonical commutation relations. In this case the lower bound given above is indeed the lowest eigenvalue of the quadratic operator. In our case the operators b and b^* only satisfy the commutation inequalities (38).

We can now apply Bogolubov's method as formulated in the theorem above to the quadratic Hamiltonian H_Q.

8.3 LEMMA (Lower bound on the quadratic Hamiltonian).

The quadratic Hamiltonian satisfies the lower bound

$$H_Q \geq -\gamma_{\varepsilon,t}^{-1/4} I_0 \nu^{5/4} \ell^{-3/4} - \tfrac{1}{2}\left(\nu^+ - \nu^-\right)^2 \widehat{w}_{00,00} - Ct^{-6}\nu\ell^{-1}, \tag{42}$$

where I_0 was defined in (5). Likewise,

$$H_{\text{Foldy}} \geq -\gamma_{\varepsilon,t}^{-1/4} I_0 \nu^{5/4} \ell^{-3/4} - Ct^{-6}\nu\ell^{-1}. \tag{43}$$

Moreover,

$$H_{\text{Foldy}} \geq \sum_{i=1}^{N} \frac{\gamma_{\varepsilon,t}}{4}\mathcal{K}_i - C\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1}. \tag{44}$$

Proof. We shall use (39). Note first that

$$\sum_{p,q\neq 0} \widehat{w}_{pq,00}(a_{p+}^* a_{q+} + a_{p-}^* a_{q-}) \leq 4\pi\ell^{-3}R^2(\nu - \widehat{n}) \leq 4\pi\ell^{-1}\nu,$$

by (32) and the fact that $R \leq \ell$.

By (40) and Theorem 8.2 with $\mathcal{B}_\pm = \nu^\pm$, $\kappa = (\nu^+ - \nu^-)\widehat{\chi}(k)\ell^{-3}$, and

$$\mathcal{A} = \left(\frac{\hat{V}_{r,R}(k)}{2(2\pi)^3}\right)^{-1} (2\pi)^{-3}\frac{\ell^3\gamma_{\varepsilon,t}}{4}\frac{|k|^4}{|k|^2 + (\ell t^6)^{-2}},$$

we have

$$
\begin{aligned}
h_Q(k) \;\geq\; & \frac{\hat{V}_{r,R}(k)}{2(2\pi)^3}\left(-(\mathcal{A} + \nu) + \sqrt{(\mathcal{A} + \nu)^2 - \nu^2}\right) - (\nu^+ - \nu^-)^2\left|\widehat{\chi}(k)\right|^2\ell^{-6}\right) \\
=\; & -\tfrac{1}{2}(2\pi)^{-3}\left(g(k) + \widetilde{f}(k) - \left(\left(g(k) + \widetilde{f}(k)\right)^2 - g(k)^2\right)^{1/2}\right) \\
& -\frac{\hat{V}_{r,R}(k)}{2(2\pi)^3\ell^6}(\nu^+ - \nu^-)^2\left|\widehat{\chi}(k)\right|^2,
\end{aligned}
$$

where

$$g(k) = \nu \hat{V}_{r,R}(k), \quad \widetilde{f}(k) = \frac{\ell^3 \gamma_{\varepsilon,t}}{2} \frac{|k|^4}{|k|^2 + (\ell t^6)^{-2}}.$$

Since

$$g(k) = 4\pi\nu \left((k^2 + R^2)^{-1} - (k^2 + r^2)^{-1}\right) \le 4\pi\nu|k|^{-2}$$

and the expression $g + \widetilde{f} - ((g + \widetilde{f})^2 - g^2)^{1/2}$ is increasing in g for fixed $\widetilde{f}$ we have

$$h_Q(k) \ge -\tfrac{1}{2}(2\pi)^{-3} \left(4\pi\nu|k|^{-2} + \widetilde{f}(k) - \left(\left(4\pi\nu|k|^{-2} + \widetilde{f}(k)\right)^2 - (4\pi\nu)^2|k|^{-4}\right)^{1/2}\right)$$

$$-\frac{\hat{V}_{r,R}(k)}{2(2\pi)^3 \ell^6}(\nu^+ - \nu^-)^2 \left|\widehat{\chi}(k)\right|^2.$$

If we now replace k by $\nu^{1/4}\ell^{-3/4}\gamma_{\varepsilon,t}^{-1/4}k$, in the k-integration, and observe that

$$\int \frac{\hat{V}_{r,R}(k)}{2(2\pi)^3 \ell^6} \left|\widehat{\chi}_\ell(k)\right|^2 \, dk$$

$$= \tfrac{1}{2}\ell^{-6} \iint \chi_\ell(x) V_{r,R}(x-y)\chi_\ell(y) \, dx \, dy = \tfrac{1}{2}\widehat{w}_{00,00},$$

we arrive at

$$H_Q \ge -\gamma_{\varepsilon,t}^{-1/4} I\nu^{5/4}\ell^{-3/4} - \tfrac{1}{2}\left(\nu^+ - \nu^-\right)^2 \widehat{w}_{00,00} - 4\pi\nu\ell^{-1}$$

where

$$I = \tfrac{1}{2}(2\pi)^{-3} \int_{\mathbb{R}^3} 4\pi|k|^{-2} + f(k) - \left((4\pi|k|^{-2} + f(k))^2 - (4\pi)^2|k|^{-4}\right)^{1/2} \, dk \qquad (45)$$

with

$$f(k) = \tfrac{1}{2}\frac{|k|^4}{|k|^2 + \gamma_{\varepsilon,t}^{1/2}(\nu\ell)^{-1/2}t^{-12}}.$$

We now study the I-integral in more details. Since the integrand is monotone decreasing in f we get an upper bound to I if we replace f by a lower bound. Let $a = \tfrac{1}{2}\gamma_{\varepsilon,t}^{1/2}(\nu\ell)^{-1/2}t^{-12}$. If $|k| \le (8a)^{1/2}$ we shall simply replace f by 0. If $|k| > (8a)^{1/2}$ we replace f by the lower bound

$$\tfrac{1}{2}|k|^2 - a.$$

Note that

$$\left((4\pi|k|^{-2} + \tfrac{1}{2}|k|^2 - a)^2 - (4\pi)^2|k|^{-4}\right)^{1/2} = \left(\tfrac{1}{4}|k|^4 + 4\pi + a^2 - (|k|^2 + 8\pi|k|^{-2})a\right)^{1/2}$$

$$\ge \left(\left(\tfrac{1}{4}|k|^4 + 4\pi\right)\left(1 - 4|k|^{-2}a\right) + a^2\right)^{1/2}$$

$$\ge \left(\tfrac{1}{4}|k|^4 + 4\pi\right)^{1/2}\left(1 - 2|k|^{-2}a + \frac{a^2}{2(|k|^4/4 + 4\pi)} - \frac{1}{8}\left(4|k|^{-2}a - \frac{a^2}{(|k|^4/4 + 4\pi)}\right)^2\right).$$

If $|k| > (8a)^{1/2}$ then $4|k|^{-2}a \ge a^2(|k|^4/4 + 4\pi)^{-1}$ and hence in this case

$$\left((4\pi|k|^{-2} + \tfrac{1}{2}|k|^2 - a)^2 - (4\pi)^2|k|^{-4}\right)^{1/2}$$

$$\ge \left(\tfrac{1}{4}|k|^4 + 4\pi\right)^{1/2} - 2|k|^{-2}a\left(\tfrac{1}{4}|k|^4 + 4\pi\right)^{1/2} + \frac{a^2}{2(|k|^4/4 + 4\pi)^{1/2}} - 2|k|^{-4}a^2\left(\tfrac{1}{4}|k|^4 + 4\pi\right)^{1/2}$$

$$\ge \left(\tfrac{1}{4}|k|^4 + 4\pi\right)^{1/2} - a - Ca|k|^{-4} - C|k|^{-6}a^2 \ge \left(\tfrac{1}{4}|k|^4 + 4\pi\right)^{1/2} - a - Ca|k|^{-4}.$$

Thus

$$
\begin{aligned}
I &\leq \tfrac{1}{2}(2\pi)^{-3}\Big(\int\limits_{|k|<(8a)^{1/2}} 4\pi|k|^{-2}\,dk + \int\limits_{|k|>(8a)^{1/2}} 4\pi|k|^{-2} + \tfrac{1}{2}|k|^2 - \big(\tfrac{1}{4}|k|^4 + 4\pi\big)^{1/2} + C|k|^{-4}a\,dk\Big) \\
&\leq \tfrac{1}{2}(2\pi)^{-3}\int_{\mathbb{R}^3} 4\pi|k|^{-2} + \tfrac{1}{2}|k|^2 - \big(\tfrac{1}{4}|k|^4 + 4\pi\big)^{1/2}\,dk + Ca^{1/2} \\
&= I_0 + C(\nu\ell)^{-1/4}t^{-6} \leq I_0 + C\nu^{-5/4}\ell^{3/4}t^{-6}\nu\ell^{-1}.
\end{aligned}
$$

This gives the stated lower bound on H_Q. The proof of (43) is similar except that one should simply use Theorem 8.2 with $\kappa = 0$. The proof of (44) is the same as the proof of (43) except that we, when proving the lower bound on H_{Foldy}, replace $\mathcal{K}$ by $\mathcal{K}/2$ and simply keep the other half $\mathcal{K}/2$ in the lower bound. Note that this will of course change the constants in the lower bound. $\qquad\square$

9 A-priori bounds on the kinetic energy, non-neutrality, and excitations

In this section we shall estimate the kinetic energy $\langle \sum_{i=1}^{N} \mathcal{K}_i \rangle$, the non-neutrality $\langle (\widehat{n}^+ - \widehat{n}^-)^2 \rangle$, and the excitations $\langle \nu - \widehat{n} \rangle$ in a state for which the energy expectation $\langle \widetilde{H} \rangle$ is low. (Recall that $\widetilde{H}$ was defined in (22) and that we are omitting the subscript z.) More precisely, we shall introduce cutoffs

$$
R = \omega(t)^{-1}\ell \quad \text{and} \quad r = \ell^{3/2}(\nu\ell)^{-1/2}. \tag{46}
$$

and consider a state such that $\langle \widetilde{H}^{\varepsilon/4}_{r,R} \rangle \leq 0$. For technical reasons this assumption will be more appropriate later (see Lemma 10.1). The Lemmas 6.3,7.1,7.2,7.4,7.5 (Eq. (33)), and 7.6 together with (44) in Lemma 8.3 control all terms in the Hamiltonian $\widetilde{H}^{\varepsilon/4}_{r,R}$ from (27). If we combine all these estimates and assume that we have further cutoffs $0 < r \leq r' \leq R' \leq R$ we obtain the following bound

$$
\begin{aligned}
\widetilde{H}^{\varepsilon/4}_{r,R} \geq\; & \sum_{i=1}^{N} -\frac{\gamma_{\varepsilon,t}}{4}\varepsilon\Delta_{i,\text{Neu}} + \sum_{i=1}^{N}\frac{\gamma_{\varepsilon,t}}{4}\mathcal{K}_i - C\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1} \\
& -\tfrac{1}{2}\nu R'^{-1} - C\nu^{+}\nu^{-}(\varepsilon^{-3/2}r'^{1/2} + \ell^{-3}r'^2) \\
& +\tfrac{1}{2}\widehat{w}'_{00,00}\big[(\widehat{n}^+ - \widehat{n}^-)^2 - \widehat{n}^+ - \widehat{n}^-\big] - 4\pi R'^2\ell^{-3}|\widehat{n}^+ - \widehat{n}^-|(\nu - \widehat{n}) \\
& +\tfrac{1}{2}\sum_{\alpha}\Big(\sum_{p\mu\neq 0} J'^{\alpha}_{p\mu}(a^*_{p+}a_{\mu+} - a^*_{p-}a_{\mu-})\Big)^2 - \tfrac{1}{2}r'^{-1}(\nu - \widehat{n}) - 2\varepsilon'\widehat{w}'_{00,00}\big((\widehat{n}^+ - \widehat{n}^-)^2 + 1\big) \\
& -\varepsilon'^{-1}8\pi\ell^{-3}R'^2(\widehat{n} + 1)(\nu - \widehat{n}) - 2\varepsilon'\sum_{\alpha}\Big(\sum_{p\mu\neq 0} J'^{\alpha}_{p\mu}(a^*_{p+}a_{\mu+} - a^*_{p-}a_{\mu-})\Big)^2.
\end{aligned}
$$

The prime on $\widehat{w}'_{00,00}$ and J' refers to the fact that these quantities are calculated with the r' and R' cutoffs. If we choose $\varepsilon' = 1/8$ and use $\widehat{w}'_{00,00} \leq 4\pi R'^2\ell^{-3}$ we arrive at

$$
\widetilde{H}^{\varepsilon/4}_{r,R} \geq \sum_{i=1}^{N} -\frac{\gamma_{\varepsilon,t}}{4}\varepsilon\Delta_{i,\text{Neu}} + \sum_{i=1}^{N}\frac{\gamma_{\varepsilon,t}}{4}\mathcal{K}_i - C\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1}
$$

$$-\tfrac{1}{2}\nu R'^{-1} - C\nu^2(\varepsilon^{-3/2}r'^{1/2} + \ell^{-3}r'^2) - \tfrac{1}{2}r'^{-1}(\nu - \widehat{n}) - C\ell^{-3}R'^2(\widehat{n}+1)(\nu - \widehat{n}+1)$$
$$+\tfrac{1}{4}\widehat{w}'_{00,00}(\widehat{n}^+ - \widehat{n}^-)^2. \tag{47}$$

It turns out that the quantity $\nu\ell$ is important and that the main contribution to our energy estimate will come from boxes where $\nu\ell$ is large (but not too large). We shall need the control on the kinetic energy, non-neutrality, and excitations only for boxes where $\nu\ell \geq \varepsilon\omega(t)^2$.

9.1 LEMMA (Bounds on non-neutrality and excitations).

Let R and r be as in (46). There is a constant $C_1 > 0$ such that if $C_1\varepsilon\omega(t)^2 \leq \nu\ell$ and $C_1 N\ell^3 \leq \varepsilon^3$ then for any state such that $\langle \widetilde{H}^{\varepsilon/4}_{r,R}\rangle \leq 0$ we have

$$\left\langle \sum_{i=1}^{N} \mathcal{K}_i \right\rangle \leq C\varepsilon^{-1/2}t^{-2}\nu^{5/4}\ell^{-3/4}(\nu\ell)^{1/4} \tag{48}$$

$$\langle \nu - \widehat{n}\rangle \leq C\varepsilon^{-3/2}t^{-2}(\nu\ell)^{3/2} \tag{49}$$

and

$$\langle (\widehat{n}^+ - \widehat{n}^-)^2\rangle \leq C\varepsilon^{-3/2}t^{-2}\nu(\nu\ell)^{3/2}. \tag{50}$$

Proof. We introduce the cutoffs

$$R' = a\varepsilon^{1/2}(\nu\ell)^{-1/2}\ell \quad \text{and} \quad r' = \varepsilon^{-1/4}\ell^{3/2}(\nu\ell)^{-1/4},$$

where $0 < a$ shall be specified below. We observe first that $r \leq r' \leq R'/2 \leq R/2$, which will, in particular, imply that $\widehat{w}'_{00,00} \geq C^{-1}R'^2\ell^{-3}$. That $r \leq r'$ follows from the assumption that $\nu\ell \geq C_1\varepsilon\omega(t)^2 \geq C_1\varepsilon$ if we choose $C_1 \geq 1$. That $R' \leq R$ follows from the assumption $C_1\varepsilon\omega(t)^2 \leq \nu\ell$ if we choose $C_1 \geq a^2$. Finally, $r' \leq R'/2$ follows from the assumption that $C_1 N\ell^3 \leq \varepsilon^3$ if C_1 is chosen large enough depending on a. In fact, we get that $R'/r' = a\varepsilon^{3/4}(\nu\ell)^{-1/4}\ell^{-1/2} \geq a\varepsilon^{3/4}N^{-1/4}\ell^{-3/4}$ since $\nu \leq N$.

We see that (30) implies

$$\sum_{i=1}^{N} -\frac{\gamma_{\varepsilon,t}}{4}\varepsilon\Delta_{i,\text{Neu}} \geq \tfrac{1}{4}\gamma_{\varepsilon,t}\varepsilon\pi^2\ell^{-2}(\nu - \widehat{n}).$$

From the estimate (47) we hence obtain

$$\widetilde{H}^{\varepsilon/4}_{r,R} \geq \sum_{i=1}^{N} \frac{\gamma_{\varepsilon,t}}{4}\mathcal{K}_i + \left(\tfrac{1}{4}\gamma_{\varepsilon,t}\pi^2 - \varepsilon^{-3/4}\ell^{1/2}(\nu\ell)^{1/4} - a^2 C\right)\varepsilon\ell^{-2}(\nu - \widehat{n}) + \tfrac{1}{4}\widehat{w}'_{00,00}(\widehat{n}^+ - \widehat{n}^-)^2$$
$$-C\nu^{5/4}\ell^{-3/4}\left(1 + a^{-1}\varepsilon^{-1/2}(\nu\ell)^{1/4} + \varepsilon^{-1/2}(\nu\ell)^{1/4}(1 + \varepsilon^{-9/8}\ell^{3/4}(\nu\ell)^{3/8}) + a^2\varepsilon(\nu\ell)^{-5/4}\right)$$
$$-Ct^{-6}\nu\ell^{-1}.$$

We have here used that $\widehat{n} \leq \nu$ and that we may estimate $\nu + 1 \leq 2\nu$ since we assume that $\nu \geq 1$. Since $\varepsilon^{-3}\ell^2(\nu\ell) \leq \varepsilon^{-3}N\ell^3 \leq C_1^{-1}$ we may rewrite this estimate as

$$\widetilde{H}^{\varepsilon/4}_{r,R} \geq \sum_{i=1}^{N} \frac{\gamma_{\varepsilon,t}}{4}\mathcal{K}_i + \left(\tfrac{1}{4}\gamma_{\varepsilon,t}\pi^2 - C_1^{-1/4} - a^2 C\right)\varepsilon\ell^{-2}(\nu - \widehat{n}) + \tfrac{1}{4}\widehat{w}'_{00,00}(\widehat{n}^+ - \widehat{n}^-)^2$$

$$-C\nu^{5/4}\ell^{-3/4}\Big(1 + \varepsilon^{-1/2}(\nu\ell)^{1/4}(1 + C_1^{-3/8} + a^{-1}) + a^2\varepsilon(\nu\ell)^{-5/4}\Big)$$
$$-C(t^{-14}\nu\ell^{-1} + t^{-22}\ell^{-2}).$$

If we choose a and C_1 appropriately we see that the second term on the right side above is bounded below by $C^{-1}\varepsilon\ell^{-2}(\nu - \widehat{n})$. From this and the assumption $C_1\varepsilon \le C\varepsilon t^{-8} \le \nu\ell$ (recall that $\omega(t) = Ct^{-4}$) we easily obtain (48) and (49). We obtain (50) if we use that $\widehat{w}'_{00,00} \ge C^{-1}R'^2\ell^{-3} = C^{-1}\varepsilon(\nu\ell)^{-1}\ell^{-1}$. $\qquad\square$

10 Localization of the number of excited particles

Although the bound on the expectation value $\langle \nu - \widehat{n} \rangle$ given in Lemma 9.1 is sufficient for our purposes we still need to know that $\langle (\nu - \widehat{n})^2 \rangle \sim \langle \nu - \widehat{n} \rangle^2$. We shall however not prove this for a general state with negative energy. Instead we shall show that we may change the ground state, without changing its energy expectation significantly, in such a way that the only occurring values of $\nu - \widehat{n}$ are bounded by the quantity on the right side of (49).

To do this we shall use the method of localizing large matrices in Lemma A.1 of Appendix A. Let Ψ be any normalized wave function with ν particles in the box $\{z\ell\} + [-\ell/2, \ell, 2]^3$. We may write $\Psi = \sum_{m=0}^{\nu} c_m \Psi_m$, where for all $m = 0, 1, \dots, \nu$, Ψ_m, is a normalized eigenfunctions of $\widehat{n}$ with eigenvalue m. We may now consider the $(\nu + 1) \times (\nu + 1)$ Hermitean matrix $\mathcal{A}$ with matrix elements $\mathcal{A}_{mm'} = \left(\Psi_m, \widetilde{H}_{r,R}^{\varepsilon/4} \Psi_{m'} \right)$.

We shall use Lemma A.1 for this matrix and the vector $\psi = (c_0, \dots, c_\nu)$. We shall choose M in Lemma A.1 to be given by

$$M = \text{ Integer part of } \varepsilon^{-3/2}t^{-2}(\nu\ell)^{3/2}. \tag{51}$$

With the assumption in Lemma 9.1 that $\nu\ell \ge C_1\varepsilon\omega(t)^2$ we may assume (C_1 so large) that $M > 2$. In particular, we may assume that $M \ge C^{-1}\varepsilon^{-3/2}t^{-2}(\nu\ell)^{3/2}$. With the notation in Lemma A.1 we have $\lambda = (\psi, \mathcal{A}\psi) = (\Psi, \widetilde{H}_{r,R}^{\varepsilon/4}\Psi)$. Note also that because of the structure of $\widetilde{H}_{r,R}^{\varepsilon/4}$ we have, again with the notation in Lemma A.1, that $d_k = 0$ if $k \ge 3$. Since $M > 2$ this means that the second sum in (70) vanishes. We conclude from Lemma A.1 that there exists a normalized wave function $\widetilde{\Psi}$ with the property that the only occurring values of $\nu - \widehat{n}$ belong to an interval of length M and such that

$$\left(\Psi, \widetilde{H}_{r,R}^{\varepsilon/4}\Psi \right) \ge \left(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4}\widetilde{\Psi} \right) - CM^{-2}(|d_1(\Psi)| + |d_2(\Psi)|).$$

We shall discuss $d_1 = d_1(\Psi)$ and $d_2 = d_2(\Psi)$ in detail below, but first we give the result on the localization of $\widehat{n}$ that we shall use.

10.1 LEMMA (Localization of $\widehat{n}$).

Let R and r be as in (46) and M as in (51). Let $C_1 > 0$ be the constant in Lemma 9.1 and assume that $C_1\varepsilon \le C_1\varepsilon\omega(t)^2 \le \nu\ell$ and $C_1N\ell^3 \le \varepsilon^3$. Then for any normalized wave function Ψ such that

$$\left(\Psi, \widetilde{H}_{r,R}^{\varepsilon/4}\Psi \right) \le -M^{-2}(|d_1(\Psi)| + |d_2(\Psi)|) \tag{52}$$

there exists a normalized wave function $\widetilde{\Psi}$, which is a linear combination of eigenfunctions of $\nu - \widehat{n}$ with eigenvalues less than CM only, such that

$$\left(\Psi, \widetilde{H}_{r,R}^{\varepsilon/4}\Psi\right) \geq \left(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4}\widetilde{\Psi}\right) - M^{-2}(|d_1(\Psi)| + |d_2(\Psi)|). \tag{53}$$

Here $d_1(\Psi)$ and $d_2(\Psi)$ are given as explained in Lemma A.1.

Proof. We choose $\widetilde{\Psi}$ as explained above. Then (53) holds. We also know that the possible $\widehat{n}$ values of $\widetilde{\Psi}$ range in an interval of length M. We do not know however, where this interval is located. The assumption (52) will allow us to say more about the location of the interval.

In fact, it follows from (52) and (53) that $\left(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4}\widetilde{\Psi}\right) \leq 0$. It is then a consequence of Lemma 9.1 that $\left(\widetilde{\Psi}, (\nu - \widehat{n})\widetilde{\Psi}\right) \leq CM$. This of course establishes that the allowed values of $\nu - \widehat{n}$ are less than $(C+1)M$ (which we of course just write as CM). □

Our final task in this section is to bound $d_1(\Psi)$ and $d_2(\Psi)$. We have that $d_1(\Psi) = (\Psi, \widetilde{H}_{r,R}^{\varepsilon/4}(1)\Psi)$, where $\widetilde{H}_{r,R}^{\varepsilon/4}(1)$ is the part of the Hamiltonian $\widetilde{H}_{r,R}^{\varepsilon/4}$ containing all the terms with the coefficients $\widehat{w}_{pq,\mu\nu}$ for which precisely one or three indices are 0. These are the terms bounded in Lemmas 7.5 and 7.6. These lemmas are stated as one-sided bounds. It is clear from the proof that they could have been stated as two sided bounds. Alternatively we may observe that $\widetilde{H}_{r,R}^{\varepsilon/4}(1)$ is transformed to $-\widetilde{H}_{r,R}^{\varepsilon/4}(1)$ by the unitary transform which maps all operators $a_{p\pm}^*$ and $a_{p\pm}$ with $p \neq 0$ to $-a_{p\pm}^*$ and $-a_{p\pm}$. This unitary transform leaves the estimates in Lemmas 7.5 and 7.6 invariant. We therefore immediately get the following bound on $d_1(\Psi)$.

10.2 LEMMA (Control of $d_1(\Psi)$).
With the assumptions in Lemma 10.1 we have for all $\varepsilon' > 0$

$$
\begin{aligned}
|d_1(\Psi)| \leq\ & \varepsilon'^{-1} 8\pi\ell^{-3}R^2(\Psi, (\widehat{n}+1)(\nu - \widehat{n})\Psi) + 2\varepsilon' \widehat{w}_{00,00}\left(\Psi, \left((\widehat{n}^+ - \widehat{n}^-)^2 + 1\right)\Psi\right) \\
& + 2\varepsilon' \sum_\alpha \left(\Psi, \left(\sum_{p\mu\neq0} J_{p\mu}^\alpha(a_{p+}^* a_{\mu+} - a_{p-}^* a_{\mu-})\right)^2 \Psi\right).
\end{aligned}
$$

Likewise, we have that $d_2(\Psi) = (\Psi, \widetilde{H}_{r,R}^{\varepsilon/4}(2)\Psi)$, where $\widetilde{H}_{r,R}^{\varepsilon/4}(2)$ is the part of the Hamiltonian $\widetilde{H}_{r,R}^{\varepsilon/4}$ containing all the terms with precisely two $a_{0\pm}$ or two $a_{0\pm}^*$. i.e., these are the terms in the Foldy Hamiltonian, which do not commute with $\widehat{n}$.

10.3 LEMMA (Control of d_2).
With the assumptions in Lemma 10.1 there exists a constant $C > 0$ such that

$$|d_2(\Psi)| \leq C\varepsilon^{-1/2}t^{-2}\nu^{5/4}\ell^{-3/4}(\nu\ell)^{1/4} + 8\pi\ell^{-3}R^2\left(\Psi, (\nu - \widehat{n})(\widehat{n}+1)\Psi\right).$$

Proof. We consider the unitary transform that replaces all the operators $a_{p\pm}^*$ and $a_{p\pm}$ with $p \neq 0$ by $-ia_{p\pm}^*$ and $ia_{p\pm}$ respectively. Under this transformation the Foldy Hamiltonian (35) changes

into an operator that differs from the Foldy Hamiltonian only by a change of sign on the part that we denoted $\widetilde{H}_{r,R}^{\varepsilon/4}(2)$. Since both operators satisfy the bound in (43) we conclude that

$$
\begin{aligned}
|d_2(\Psi)| \quad \leq \quad & \sum_{i=1}^{N} \frac{\gamma_{\varepsilon,t}}{2} \left(\Psi, \mathcal{K}_i \Psi \right) + \tfrac{1}{2} \sum_{pq \neq 0} \widehat{w}_{pq,00} \bigg(\Psi, \Big(2a_{p+}^* a_{0+}^* a_{0+} a_{q+} + 2a_{p-}^* a_{0-}^* a_{0-} a_{q-} \\
& -2a_{p+}^* a_{0-}^* a_{q-} a_{0+} - 2a_{0+}^* a_{q-}^* a_{p+} a_{0-} \Big) \Psi \bigg) \\
& + \gamma_{\varepsilon,t}^{-1/4} I_0 \nu^{5/4} \ell^{-3/4} + C t^{-6} \nu \ell^{-1}.
\end{aligned}
$$

If we use the representation (31) we find using a Cauchy-Schwarz inequality that

$$
\begin{aligned}
& -\sum_{pq \neq 0} \widehat{w}_{pq,00} (a_{p+}^* a_{0-}^* a_{q-} a_{0+} + a_{0+}^* a_{q-}^* a_{p+} a_{0-}) = \\
& \quad -\sum_{\alpha} \left(\sum_{p \neq 0} J_{p0}^\alpha a_{p+}^* a_{0+} \Big(\sum_{q \neq 0} J_{q0}^\alpha a_{q-}^* a_{0-} \Big)^* + \sum_{q \neq 0} J_{q0}^\alpha a_{q-}^* a_{0-} \Big(\sum_{p \neq 0} J_{p0}^\alpha a_{p+}^* a_{0+} \Big)^* \right) \\
& \quad \leq \sum_{\alpha} \left(\sum_{p \neq 0} J_{p0}^\alpha a_{p+}^* a_{0+} \Big(\sum_{q \neq 0} J_{q0}^\alpha a_{q+}^* a_{0+} \Big)^* + \sum_{q \neq 0} J_{q0}^\alpha a_{q-}^* a_{0-} \Big(\sum_{p \neq 0} J_{p0}^\alpha a_{p-}^* a_{0-} \Big)^* \right) \\
& \quad = \sum_{pq \neq 0} \widehat{w}_{pq,00} \Big(a_{p+}^* (a_{0+}^* a_{0+} + 1) a_{q+} + a_{p-}^* (a_{0-}^* a_{0-} + 1) a_{q-} \Big).
\end{aligned}
$$

The lemma now follows from (32) and from Lemma 9.1. □

11 Lower bound on the energy in a small cube

Our goal in this section is to prove a lower bound on the expectation $\langle \widetilde{H} \rangle = (\Psi, \widetilde{H}\Psi)$ of the operator $\widetilde{H}$ from (22). We are aiming at the following result.

11.1 THEOREM (Lower bound on $\widetilde{H}$). *There exists a constant $C_0 > 0$ such that for all $0 < \varepsilon < 1$ and $0 < t < 1/2$ with $C_0 N \ell^3 \leq \varepsilon^3$, and $\varepsilon^{-1} t^{-4} \ell < C_0^{-1}$ we have the estimate*

$$
\begin{aligned}
\left\langle \widetilde{H} \right\rangle \quad \geq \quad & -\gamma_{\varepsilon,t}^{-1/4} I_0 \langle \widehat{n} \rangle^{5/4} \ell^{-3/4} - C(t^{-6} \nu \ell^{-1} + \varepsilon \ell^{-2} + \varepsilon^{-1} t^{-8} \nu) \\
& -K_1(\varepsilon, t, N, \ell) \langle \widehat{n} \rangle^{5/4} \ell^{-3/4} - \langle \widehat{n} \rangle^{5/3} \ell^{-1/3} (N^{2/5} \ell)^{-5/3} \Big(C \varepsilon^{1/6} + K_2(\varepsilon, t, N, \ell) \Big), \quad (54)
\end{aligned}
$$

where K_1 and K_2 are sums of a finite number of terms of the form $C \varepsilon^{-a} t^{-b} (N^{2/5} \ell)^c N^{-d}$ with $d > 0$.

Note that the estimate is not formulated as an operator inequality. The lower bound is not a constant nor an expectation value, but a non-linear expression in $\langle \widehat{n} \rangle$. The reason that we give the bound in terms of an expression in $\langle \widehat{n} \rangle$ rather than in terms of ν is that we shall later take into account the term $T(S_0)$, i.e., the kinetic energy between boxes, which depends on $\langle \widehat{n} \rangle$ (see (18)).

In order to arrive at an estimate expressed in $\langle \widehat{n} \rangle$ we shall make repeated use of the following result.

11.2 LEMMA. *If $\langle \widetilde{H} \rangle \leq 0$ we have the estimate*

$$\langle n \rangle \geq \nu(1 - C\varepsilon^{-1}(N^{2/5}\ell)N^{-1/15}).$$

In particular, we may assume that the constant C_1 from Lemma 9.1 is so large that if $C_1 N\ell^3 \leq \varepsilon^3$ (i.e., $(N^{2/5}\ell) \leq C_1^{-1}\varepsilon N^{1/15}$) then

$$\nu \leq C\langle \widehat{n} \rangle \quad and \quad \nu^{5/4} \leq \langle \widehat{n} \rangle^{5/4}(1 + C\varepsilon^{-1}(N^{2/5}\ell)N^{-1/15}).$$

Proof. This follows from Corollary 6.4 since $\varepsilon^{-1}\ell\nu^{1/3} \leq \varepsilon^{-1}(N^{2/5}\ell)N^{-1/15}$, where we have used that $\nu \leq N$. □

We shall prove Theorem 11.1 by dividing into several cases. We first prove an a-priori bound on $\widetilde{H}$.

11.3 LEMMA (A-prori bound on $\widetilde{H}$). *We may assume that the constant C_1 from Lemma 9.1 is large enough so that if $C_1 N\ell^3 \leq \varepsilon^3$ and $\varepsilon^{-1}t^{-4}\ell < C_1^{-1}$ there exists a constant $C > 0$ such that*

$$\widetilde{H} \geq -\gamma_{\varepsilon,t}^{-1/4}I_0\nu^{5/4}\ell^{-3/4} - C\nu^{5/4}\ell^{-3/4}\left(\varepsilon^{-1/2}(\nu\ell)^{1/4} + \varepsilon^{-2}(\nu\ell)^{3/4}\ell\right) - C(t^{-6}\nu\ell^{-1} + \varepsilon\ell^{-2}). \quad (55)$$

Proof. If $\nu = 0$ there is nothing to prove. We may therefore assume that $\nu \geq 1$. We now make the following choices for the cutoffs

$$r = b\varepsilon^{-1}\ell^2 \quad and \quad R = \min\{a\varepsilon^{1/2}(\nu\ell)^{-1/2}, \omega(t)^{-1}\}\ell,$$

where $0 < a, b$ shall be specified below. We first note that $r \leq R$ if C_1 is sufficiently large (depending on a and b). Indeed, either $R/r = (a/b)(\varepsilon^3\nu^{-1}\ell^{-3})^{1/2} \geq (a/b)C_1^{1/2}$ (since $\nu \leq N$) or $R/r = b^{-1}\omega(t)^{-1}\varepsilon\ell^{-1} \geq C^{-1}b^{-1}t^4\varepsilon\ell^{-1} \geq b^{-1}C^{-1}C_1$.

We proceed as in the beginning of Sect. 9, but we now use Lemma 6.2 instead of Lemma 6.3 and (43) instead of (44). We then get that

$$
\begin{aligned}
\widetilde{H} \geq &\sum_{i=1}^{N} -\frac{\gamma_{\varepsilon,t}}{2}(\varepsilon - \delta)\Delta_{i,\text{Neu}} - \gamma_{\varepsilon,t}^{-1/4}I_0\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1} - C\nu R^{-1} \\
&- C\nu^2(\delta^{-3/2}r^{1/2} + \ell^{-3}r^2) + \tfrac{1}{2}\widehat{w}_{00,00}\left[(\widehat{n}^+ - \widehat{n}^-)^2 - \widehat{n}^+ - \widehat{n}^-\right] - 4\pi R^2\ell^{-3}|\widehat{n}^+ - \widehat{n}^-|(\nu - \widehat{n}) \\
&+ \tfrac{1}{2}\sum_{\alpha}\left(\sum_{p\mu\neq 0} J_{p\mu}^{\alpha}(a_{p+}^*a_{\mu+} - a_{p-}^*a_{\mu-})\right)^2 - \tfrac{1}{2}r^{-1}(\nu - \widehat{n}) - 2\varepsilon'\widehat{w}_{00,00}\left((\widehat{n}^+ - \widehat{n}^-)^2 + 1\right) \\
&- \varepsilon'^{-1}8\pi\ell^{-3}R^2(\widehat{n} + 1)(\nu - \widehat{n}) - 2\varepsilon'\sum_{\alpha}\left(\sum_{p\mu\neq 0} J_{p\mu}^{\alpha}(a_{p+}^*a_{\mu+} - a_{p-}^*a_{\mu-})\right)^2.
\end{aligned}
$$

If we Choose $\varepsilon' = 1/4$, use that $\widehat{w}_{00,00} \leq 4\pi R^2\ell^{-3}$, and $\widehat{n} \leq \nu$ we obtain after inserting the choices of r and R that

$$
\begin{aligned}
\widetilde{H} \geq &\sum_{i=1}^{N} -\frac{\gamma_{\varepsilon,t}}{2}(\varepsilon - \delta)\Delta_{i,\text{Neu}} - \gamma_{\varepsilon,t}^{1/4}I_0\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1} - \tfrac{1}{2}\varepsilon^{-1}a^{-1}\nu\ell^{-1}(\nu\ell)^{1/2} \\
&- C\nu^2\ell(b^{1/2}\varepsilon^{-1/2}\delta^{-3/2} + \varepsilon^{-2}b^2) - \tfrac{1}{2}\varepsilon b^{-1}(\nu - \widehat{n})\ell^{-2} - a^2\varepsilon C\ell^{-1}(\nu\ell)^{-1}\nu(\nu - \widehat{n} + 1).
\end{aligned}
$$

We have here inserted the upper bound $a\varepsilon(\nu\ell)^{-1/2}\ell$ for R. This is allowed, since the only term which is not monotone increasing in R, i.e., $\frac{1}{2}\nu R^{-1}$, can in fact, according to (29), be ignored when $R = \omega(t)^{-1}\ell$. We have again replaced $\nu + 1$ by 2ν.

If we now choose $\delta = \varepsilon/2$, and again use that

$$\sum_{i=1}^{N} -\frac{\gamma_{\varepsilon,t}}{2}(\varepsilon - \delta)\Delta_{i,\mathrm{Neu}} \geq \tfrac{1}{4}\gamma_{\varepsilon,t}\varepsilon\pi^2\ell^{-2}(\nu - \widehat{n}),$$

we arrive at

$$\begin{aligned}
\widetilde{H} \geq{}& \left(\tfrac{1}{4}\gamma_{\varepsilon,t}\pi^2 - b^{-1}/2 - a^2 C\right)\varepsilon\ell^{-2}(\nu - \widehat{n}) - \gamma_{\varepsilon,t}^{1/4}I_0\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1} \\
& -C\nu^{5/4}\ell^{-3/4}\left(a^{-1}\varepsilon^{-1/2}(\nu\ell)^{1/4} + \varepsilon^{-2}(b^{1/2} + b^2)(\nu\ell)^{3/4}\ell + a^2\varepsilon(\nu\ell)^{-5/4}\right).
\end{aligned}$$

We obtain the results of the lemma if we make appropriate choices of a and b. $\qquad\square$

We now use this estimate to control boxes with few or with many particles. We shall show that these boxes do not contribute to the leading order estimate of the energy. Thus the specific form of the first term in (55) is not important. We may simply estimate it by $C\nu^{5/4}\ell^{-3/4}$.

11.4 LEMMA (Boxes with few particles).
Let C_1 be the constant in Lemma 9.1 and assume that $\nu\ell \leq C_1\varepsilon\omega(t)^2$, $C_1 N\ell^3 \leq \varepsilon^3$, and $\varepsilon^{-1}t^{-4}\ell < C_1^{-1}$. Then there is a constant $C > 0$ such that

$$\widetilde{H} \geq -Ct^{-14}\nu\ell^{-1} - C\varepsilon\ell^{-2} - C\varepsilon^{-1}t^{-8}\nu.$$

Proof. The result follows immediately from Lemma 11.3 if we simply insert the assumed bound on $\nu\ell$ and use that $\omega(t) = Ct^{-4}$. $\qquad\square$

11.5 LEMMA (Boxes with many particles). *Let C_1 be the constant in Lemma 9.1. Assume that $\nu\ell \geq \varepsilon^{-4}(N^{2/5}\ell)^{10}$, $C_1 N\ell^3 \leq \varepsilon^3$, and $\varepsilon^{-1}t^{-4}\ell < C_1^{-1}$. Then*

$$\begin{aligned}
\langle\widetilde{H}\rangle \geq{}& -\gamma_{\varepsilon,t}^{-1/4}I_0\langle\widehat{n}\rangle^{5/4}\ell^{-3/4} - C\langle\widehat{n}\rangle^{5/4}\ell^{-3/4}\varepsilon^{-1}(N^{2/5}\ell)N^{-1/15} \\
& -C\langle\widehat{n}\rangle^{5/3}\ell^{-1/3}\left(\varepsilon^{1/6}(N^{2/5}\ell)^{-5/3} + \varepsilon^{-2}(N^{2/5}\ell)^{4/3}N^{-3/15}\right) \\
& -C(t^{-14}\nu\ell^{-1} + t^{-22}\ell^{-2}).
\end{aligned}$$

Proof. We may of course assume that $\langle\widetilde{H}\rangle \leq 0$ and hence use the estimates in Lemma 11.2. We now use Lemma 11.3 and insert the estimates

$$\begin{aligned}
\nu^{5/4}\ell^{-3/4}(\nu\ell)^{1/4} &= \nu^{5/3}\ell^{-1/3}(\nu\ell)^{-1/6} \leq \nu^{5/3}\ell^{-1/3}\varepsilon^{2/3}(N^{2/5}\ell)^{-5/3} \\
\nu^{5/4}\ell^{-3/4}(\nu\ell)^{3/4}\ell &= \nu^{5/3}\ell^{-1/3}\nu^{1/3}\ell^{4/3} \leq \nu^{5/3}\ell^{-1/3}(N^{2/5}\ell)^{4/3}N^{-3/15}.
\end{aligned}$$

In the first inequality we used the assumption on $\nu\ell$. In the last inequality we simply used that $\nu \leq N$. $\qquad\square$

We now restrict attention to boxes with $\varepsilon\omega(t)^2 \le \nu\ell \le \varepsilon^{-4}(N^{2/5}\ell)^{10}$. In the next lemma we shall prove the lower bound on $\langle\widetilde{H}\rangle$ under the restrictive assumption given in (56) below. Finally, Theorem 11.1 is proved by considering the alternative case that (56) fails. Let us note that, logically speaking, this could have been done in the reverse order. I.e., we could, instead, have begun with the case that (56) fails.

11.6 LEMMA (Lower bound on $\widetilde{H}$: restricted version). *Let R and r be given by (46). Let C_1 be the constant in Lemma 9.1. Assume that $C_1\varepsilon\omega(t)^2 \le \nu\ell \le \varepsilon^{-4}(N^{2/5}\ell)^{10}$ and $C_1 N\ell^3 \le \varepsilon^3$. Then there exists a constant $C_2 > 0$ such that if*

$$\ell^{-3}R^2\nu\langle\nu - \widehat{n}\rangle \tag{56}$$
$$\le C_2^{-1}\left\langle \widehat{w}_{00,00}(\widehat{n}^+ - \widehat{n}^-)^2 + \sum_\alpha\left(\sum_{p\mu\neq 0} J_{p\mu}^\alpha(a_{p+}^*a_{\mu+} - a_{p-}^*a_{\mu-})\right)^2\right\rangle,$$

we have that

$$\left\langle\widetilde{H}\right\rangle \ge -\gamma_{\varepsilon,t}^{-1/4}I_0\langle\widehat{n}\rangle^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1}$$
$$-C\langle\widehat{n}\rangle^{5/4}\ell^{-3/4}\left(\varepsilon^{-1}(N^{2/5}\ell)N^{-1/15} + \varepsilon^{-7/2}(N^{2/5}\ell)^{23/4}N^{-3/10}\right.$$
$$\left. + \varepsilon^{-9/2}t^{-2}(N^{2/5}\ell)^8 N^{-1/5}\right).$$

Proof. We may of course assume that $\langle\widetilde{H}\rangle \le 0$ and hence use Lemma 11.2. We may also assume that $\langle\widetilde{H}_{r,R}^{\varepsilon/4}\rangle \le 0$ otherwise we have from (29) and the choice of r that

$$\langle\widetilde{H}\rangle \ge -C\nu^2(\varepsilon^{-3/2}r^{1/2} + \ell^{-3}r^2) = -C\varepsilon^{-3/2}\nu^{5/4}\ell^{-3/4}(\nu\ell)^{1/2}\ell^{3/4} - C\nu\ell^{-1}$$
$$\ge -C\varepsilon^{-3/2}\langle\widehat{n}\rangle^{5/4}\ell^{-3/4}(\varepsilon^{-4}(N^{2/5}\ell)^{10})^{1/2}(N^{2/5}\ell)^{3/4}N^{-3/10} - C\nu\ell^{-1}$$
$$= -C\langle\widehat{n}\rangle^{5/4}\varepsilon^{-7/2}\ell^{-3/4}(N^{2/5}\ell)^{23/4}N^{-3/10} - C\nu\ell^{-1},$$

which implies the stated estimate. It now follows from Lemma 9.1 that we have the estimate (49).

We again proceed as in the beginning of Sect. 9, but we use (43) instead of (44) and (29) instead of Lemma 6.3 or (28) (since now $R = \omega(t)^{-1}\ell$) and we choose $\delta = \varepsilon$. We then get that

$$\widetilde{H} \ge -\gamma_{\varepsilon,t}^{-1/4}I_0\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1} - C\nu^2(\varepsilon^{-3/2}r^{1/2} + \ell^{-3}r^2)$$
$$+ \tfrac{1}{2}\widehat{w}_{00,00}\left[(\widehat{n}^+ - \widehat{n}^-)^2 - \widehat{n}^+ - \widehat{n}^-\right] - 4\pi R^2\ell^{-3}|\widehat{n}^+ - \widehat{n}^-|(\nu - \widehat{n})$$
$$+ \tfrac{1}{2}\sum_\alpha\left(\sum_{p\mu\neq 0} J_{p\mu}^\alpha(a_{p+}^*a_{\mu+} - a_{p-}^*a_{\mu-})\right)^2 - \tfrac{1}{2}r^{-1}(\nu - \widehat{n}) - 2\varepsilon'\widehat{w}_{00,00}\left((\widehat{n}^+ - \widehat{n}^-)^2 + 1\right)$$
$$-\varepsilon'^{-1}8\pi\ell^{-3}R^2(\widehat{n} + 1)(\nu - \widehat{n}) - 2\varepsilon'\sum_\alpha\left(\sum_{p\mu\neq 0} J_{p\mu}^\alpha(a_{p+}^*a_{\mu+} - a_{p-}^*a_{\mu-})\right)^2.$$

If we use the assumption (56) and the facts that $|\widehat{n}^+ - \widehat{n}^-| \le \nu$, $\widehat{n} + 1 \le 2\nu$, and $\widehat{w}_{00,00} \le 4\pi R^2\ell^{-3}$ we see with appropriate choices of ε' and C_2 that

$$\langle\widetilde{H}\rangle \ge -\gamma_{\varepsilon,t}^{-1/4}I_0\nu^{5/4}\ell^{-3/4} - C(t^{-14}\nu\ell^{-1} + t^{-22}\ell^{-2})$$
$$-C\varepsilon^{-3/2}\nu^{7/4}\ell^{1/2} - C\nu\ell^{-1} - C\omega(t)^{-2}\nu\ell^{-1} - C\langle\nu - \widehat{n}\rangle\nu^{1/2}\ell^{-1},$$

where we have inserted the choices of r and R. If we use (49) we see that

$$\langle \nu - \widehat{n} \rangle \nu^{1/2} \ell^{-1} \leq C\varepsilon^{-3/2} t^{-2} \nu^{5/4} \ell^{-3/4} (\nu\ell)^{3/4} \ell^{1/2} \leq C\varepsilon^{-9/2} t^{-2} \nu^{5/4} \ell^{-3/4} (N^{2/5}\ell)^8 N^{-1/5}.$$

Hence we arrive at the bound in the lemma if we note, as above, that

$$\varepsilon^{-3/2} \nu^{7/4} \ell^{1/2} \leq C\nu^{5/4} \ell^{-3/4} \varepsilon^{-7/2} (N^{2/5}\ell)^{23/4} N^{-3/10}$$

and use the result of Lemma 11.2. $\qquad\square$

Proof of Theorem 11.1. We again let r and R be given by (46). According to Lemmas 11.4 and 11.5 we may assume that $C_1 \varepsilon \omega(t)^2 \leq \nu\ell \leq \varepsilon^{-4}(N^{2/5}\ell)^{10}$. Then from Lemma 11.6 we may assume that

$$\ell^{-3} R^2 \nu \langle \nu - \widehat{n} \rangle \tag{57}$$
$$\geq C_2^{-1} \left\langle \widehat{w}_{00,00}(\widehat{n}^+ - \widehat{n}^-)^2 + \sum_\alpha \left(\sum_{p\mu \neq 0} J_{p\mu}^\alpha (a_{p+}^* a_{\mu+} - a_{p-}^* a_{\mu-}) \right)^2 \right\rangle.$$

We may also still assume that $\langle \widetilde{H} \rangle \leq 0$ and $\langle \widetilde{H}_{r,R}^{\varepsilon/4} \rangle \leq 0$ (as in the proof of Lemma 11.6). Hence we can use the results of Lemmas 9.1 and 11.2. It is enough to prove an estimate of the type (54) for $\langle \widetilde{H}_{r,R}^{\varepsilon/4} \rangle$ (the extra error terms were estimated in the first paragraph of the proof of Lemma 11.6).

We begin by bounding d_1 and d_2 using Lemmas 10.2 and 10.3. We have from Lemmas 9.1 and 10.3 that

$$\begin{aligned} |d_2| &\leq C\varepsilon^{-1/2} t^{-2} \nu^{5/4} \ell^{-3/4} (\nu\ell)^{1/4} + C\ell^{-3} R^2 \nu \langle \nu - \widehat{n} \rangle \\ &\leq C\nu^{5/4} \ell^{-3/4} \left(\varepsilon^{-1/2} t^{-2} (\nu\ell)^{1/4} + t^6 \varepsilon^{-3/2} (\nu\ell)^{5/4} \right) \leq Ct^6 \varepsilon^{-3/2} \nu^{5/4} \ell^{-3/4} (\nu\ell)^{5/4}, \end{aligned}$$

where the last estimate follows since $\nu\ell \geq \varepsilon\omega(t)^2$.

In order to bound d_1 we shall use (57). Together with Lemma 10.2 this gives (choosing $\varepsilon' = 1/2$ say)

$$|d_1| \leq C\ell^{-3} R^2 \nu (\langle \nu - \widehat{n} \rangle + 1) \leq Ct^6 \varepsilon^{-3/2} \nu^{5/4} \ell^{-3/4} (\nu\ell)^{5/4}.$$

If the assumption (52) fails then

$$\langle \widetilde{H}_{r,R}^{\varepsilon/4} \rangle \geq -Ct^{10} \varepsilon^{3/2} \nu^{5/4} \ell^{-3/4} (\nu\ell)^{-7/4} \geq -Ct^{10} \varepsilon^{3/2} \nu\ell^{-1} (\varepsilon\omega(t)^2)^{-3/2} = -Ct^{22} \nu\ell^{-1}.$$

and we see then that the bound (54) holds. We may therefore assume that (52) holds. Thus from Lemma 10.1 it follows that we can find a normalized wave function $\widetilde{\Psi}$, such that

$$\left(\widetilde{\Psi}, (\nu - \widehat{n}) \widetilde{\Psi} \right) \leq C\varepsilon^{-3/2} t^{-2} (\nu\ell)^{3/2} \quad \text{and} \quad \left(\widetilde{\Psi}, (\nu - \widehat{n})^2 \widetilde{\Psi} \right) \leq C\varepsilon^{-3} t^{-4} (\nu\ell)^3 \tag{58}$$

and such that

$$\left\langle \widetilde{H}_{r,R}^{\varepsilon/4} \right\rangle \geq \left(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4} \widetilde{\Psi} \right) - Ct^{22} \nu\ell^{-1}. \tag{59}$$

(Here as before $\langle X \rangle$ denotes the expectation of the operator X in the state Ψ.)

In order to analyze $\left(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4} \widetilde{\Psi} \right)$ we again proceed as in the beginning of Sect. 9, but this time we use (34) of Lemma 7.5 and (42) of Lemma 8.3. We find that

$$
\begin{aligned}
\widetilde{H}_{r,R}^{\varepsilon/4} \geq \ & -\gamma_{\varepsilon,t}^{-1/4} I_0 \nu^{5/4} \ell^{-3/4} - Ct^{-6} \nu \ell^{-1} \\
& + \tfrac{1}{2} \widehat{w}_{00,00} \left[(\widehat{n}^+ - \widehat{n}^-)^2 - \widehat{n}^+ - \widehat{n}^- \right] - 4\pi R^2 \ell^{-3} |\widehat{n}^+ - \widehat{n}^-|(\nu - \widehat{n}) - \tfrac{1}{2} \widehat{w}_{00,00}(\nu^+ - \nu^-)^2 \\
& + \tfrac{1}{2} \sum_\alpha \left(\sum_{p\mu \neq 0} J_{p\mu}^\alpha (a_{p+}^* a_{\mu+} - a_{p-}^* a_{\mu-}) \right)^2 - \tfrac{1}{2} r^{-1}(\nu - \widehat{n}) - 2\varepsilon' \widehat{w}_{00,00} \left((\nu - \widehat{n})^2 + 1 \right) \\
& - \varepsilon'^{-1} 8\pi \ell^{-3} R^2 (\widehat{n} + 1)(\nu - \widehat{n}) - 2\varepsilon' \sum_\alpha \left(\sum_{p\mu \neq 0} J_{p\mu}^\alpha (a_{p+}^* a_{\mu+} - a_{p-}^* a_{\mu-}) \right)^2 . \qquad (60)
\end{aligned}
$$

We shall use that for all $\varepsilon'' > 0$

$$
(\nu^+ - \nu^-)^2 \leq (1 + \frac{\varepsilon''}{2})(\widehat{n}^+ - \widehat{n}^-)^2 + (1 + \frac{1}{2\varepsilon''})(\nu - \widehat{n})^2
$$

and

$$
|\widehat{n}^+ - \widehat{n}^-|(\nu - \widehat{n}) \leq \frac{\varepsilon''}{2}(\widehat{n}^+ - \widehat{n}^-)^2 + \frac{1}{2\varepsilon''}(\nu - \widehat{n})^2 .
$$

According to Lemma 7.4

$$
\begin{aligned}
\sum_\alpha \left(\sum_{p\mu \neq 0} J_{p\mu}^\alpha (a_{p+}^* a_{\mu+} - a_{p-}^* a_{\mu-}) \right)^2 \leq \ & \sum_{pq,\mu\nu \neq 0} \widehat{w}_{pq,\mu\nu} \Big(a_{p+}^* a_{q+}^* a_{\nu+} a_{\mu+} + a_{p-}^* a_{q-}^* a_{\nu-} a_{\mu-} \\
& - 2 a_{p+}^* a_{q-}^* a_{\nu-} a_{\mu+} \Big) + (\nu - \widehat{n}) r^{-1}
\end{aligned}
$$

The sum on the right is simply the second quantization of the two-body operator $\mathcal{P} \otimes \mathcal{P} w_{r,R} \mathcal{P} \otimes \mathcal{P}$, where $\mathcal{P}$ again denotes the projection onto the subspace of $L^2 \left(([-\ell/2, \ell/2]^3) \times \{1, -1\} \right)$ consisting of functions orthogonal to constants. Since $w_{r,R} \leq r^{-1}$ this sum is bounded above by

$$
\left((\nu^+ - \widehat{n}^+)^2 + (\nu^- - \widehat{n}^-)^2 \right) r^{-1} \leq (\nu - \widehat{n})^2 r^{-1} .
$$

(This can of course also be proved by directly estimating the sum). If we insert the above estimates into (60) and choose $\varepsilon' = 1/\varepsilon''$ we arrive at

$$
\begin{aligned}
\widetilde{H}_{r,R}^{\varepsilon/4} \geq \ & -\gamma_{\varepsilon,t}^{-1/4} I_0 \nu^{5/4} \ell^{-3/4} - Ct^{-6} \nu \ell^{-1} \\
& - CR^2 \ell^{-3} \left(\nu + \varepsilon''(\widehat{n}^+ - \widehat{n}^-)^2 + (1 + \tfrac{1}{\varepsilon''}) \left((\nu - \widehat{n})^2 + 1 \right) + \varepsilon'' \nu(\nu - \widehat{n}) \right) \\
& - Cr^{-1}(\tfrac{1}{\varepsilon''}(\nu - \widehat{n})^2 + (1 + \tfrac{1}{\varepsilon''})(\nu - \widehat{n})) .
\end{aligned}
$$

We now use (58), Lemma 9.1 (we may of course assume that $(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4} \widetilde{\Psi}) \leq 0$), and the choices (46) of R and r. We get

$$
\begin{aligned}
\left(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4} \widetilde{\Psi} \right) \geq \ & -\gamma_{\varepsilon,t}^{-1/4} I_0 \nu^{5/4} \ell^{-3/4} - Ct^{-6} \nu \ell^{-1} \\
& - C\omega(t)^{-2} \ell^{-1} \left(\nu + \varepsilon'' \varepsilon^{-3/2} t^{-2} \nu(\nu\ell)^{3/2} + (1 + \tfrac{1}{\varepsilon''}) \varepsilon^{-3} t^{-4} (\nu\ell)^3 \right) \\
& - C\ell^{-3/2}(\nu\ell)^{1/2} \left(\tfrac{1}{\varepsilon''} \varepsilon^{-3} t^{-4} (\nu\ell)^3 + (1 + \tfrac{1}{\varepsilon''}) \varepsilon^{-3/2} t^{-2} (\nu\ell)^{3/2} \right) .
\end{aligned}
$$

Finally we make the choice $\varepsilon'' = \varepsilon^{-3/4}t^{-5}(\nu\ell)^{1/2}\ell^{1/4}$ and arrive at

$$
\begin{aligned}
\left(\widetilde{\Psi}, \widetilde{H}_{r,R}^{\varepsilon/4}\widetilde{\Psi}\right) \;\geq\; & -\gamma_{\varepsilon,t}^{-1/4}I_0\nu^{5/4}\ell^{-3/4} - Ct^{-6}\nu\ell^{-1} \\
& -C\nu^{5/4}\ell^{-3/4}\Big(\varepsilon^{-9/4}t^1(\nu\ell)^{7/4}\ell^{1/4} + \varepsilon^{-3}t^4(\nu\ell)^{7/4}\ell + \varepsilon^{9/4}t^9(\nu\ell)^{5/4}\ell^{3/4} \\
& \qquad\qquad + \varepsilon^{-3/2}t^{-2}(\nu\ell)^{3/4}\ell^{1/2} + \varepsilon^{-3/4}t^3(\nu\ell)^{1/4}\ell^{1/4}\Big).
\end{aligned}
$$

If we now insert the bound $\nu\ell \leq \varepsilon^{-4}(N^{2/5}\ell)^{10}$, use (59) and the result of Lemma 11.2 we arrive at a bound of the form (54) for $\langle\widetilde{H}_{r,R}^{\varepsilon/4}\rangle$. $\qquad\square$

12　The lattice approximation

Given a map $S : \mathbb{Z}^3 \to \mathbb{R}$ we define a function $\phi : \mathbb{R}^3 \to \mathbb{R}$ as follows. On any cube $\{\mu\} + [-1/2, 1/2]^3$ with $\mu \in \{(1/2, 1/2, 1/2)\} + \mathbb{Z}^3$ we set

$$
\phi(x) = \sum_{\substack{\tau\in\mathbb{Z}^3 \\ |\tau|=\sqrt{3}}} \lambda_\tau(x - \mu)S(\mu + \tau/2), \tag{61}
$$

where

$$
\lambda_\tau(x) = (1/2 + \tau_1 x_1)(1/2 + \tau_2 x_2)(1/2 + \tau_3 x_3). \tag{62}
$$

Note that the 8 points $\mu + \tau/2$ with $|\tau| = \sqrt{3}$ are the corners of the cube $\{\mu\} + [-1/2, 1/2]^3$. The function ϕ is well-defined on $\mathbb{R}^3$ and is continuous. Moreover, $\phi(\sigma) = S(\sigma)$ for $\sigma \in \mathbb{Z}^3$. By a straightforward calculation we obtain that

$$
\int_{\mathbb{R}^3} (\nabla\phi)^2 = T(S), \tag{63}
$$

where we have defined

$$
T(S) = \sum_{\substack{\sigma_1,\sigma_2\in\mathbb{Z}^3 \\ |\sigma_1-\sigma_2|=\sqrt{2}}} \frac{1}{12}(S(\sigma_1) - S(\sigma_2))^2 + \sum_{\substack{\sigma_1,\sigma_2\in\mathbb{Z}^3 \\ |\sigma_1-\sigma_2|=\sqrt{3}}} \frac{1}{24}(S(\sigma_1) - S(\sigma_2))^2.
$$

Note that there is a constant $C > 0$ such that for all maps $S : \mathbb{Z}^3 \to \mathbb{R}$ we have

$$
C^{-1} \sum_{\substack{\sigma_1,\sigma_2\in\mathbb{Z}^3 \\ |\sigma_1-\sigma_2|=1}} (S(\sigma_1) - S(\sigma_2))^2 \leq T(S) \leq C \sum_{\substack{\sigma_1,\sigma_2\in\mathbb{Z}^3 \\ |\sigma_1-\sigma_2|=1}} (S(\sigma_1) - S(\sigma_2))^2.
$$

12.1 LEMMA. *If $\lambda_1,\ldots,\lambda_m \geq 0$ and $\sum_{j=1}^m \lambda_j = 1$ we have for all $S_1,\ldots,S_m \geq 0$ and all $\beta \geq 1$ that*

$$
\left(\sum_{j=1}^m \lambda_j S_j\right)^\beta \leq \sum_{j=1}^m \lambda_j S_j^\beta \leq \left(\sum_{j=1}^m \lambda_j S_j\right)^\beta + C_{m,\beta}\left(\sum_{1\leq i<j\leq m} (S_i - S_j)^2\right)^{1/2} \sum_{j=1}^m S_j^{\beta-1}
$$

for some constant $C_{m,\beta} > 0$.

Proof. The first inequality follows from an application of Jensen's inequality. If we write $Y = \sum_{j=1}^{m} \lambda_j S_j$ then $\sum_{j=1}^{m} \lambda_j S_j^\beta - \left(\sum_{j=1}^{m} \lambda_j S_j\right)^\beta = \sum_{j=1}^{m} \lambda_j (S_j^\beta - Y^\beta)$. The second inequality above then follows easily from $|a^\beta - b^\beta| \leq \beta |a - b|(a^{\beta-1} + b^{\beta-1})$, which holds for all $a, b > 0$, and $|S_i - Y| \leq \sum_{j=1}^{m} \lambda_j |S_i - S_j|$. $\qquad\square$

12.2 LEMMA. *If $\beta \geq 2$ and if $\phi : \mathbb{R}^3 \to \mathbb{R}$ is the function constructed above corresponding to a non-negative map $S : \mathbb{Z}^3 \to \mathbb{R}$ we have for all $0 < \delta$ that*

$$(1 - \delta) \sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^\beta - C\delta^{-(\beta-1)} T(S)^{\beta/2} \leq \int_{\mathbb{R}^3} \phi^\beta \leq \sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^\beta$$

and that

$$\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^{5/2} - \delta T(S) - C\delta^{-1} \left(\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^6\right)^{1/4} \left(\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^2\right)^{3/4} \leq \int_{\mathbb{R}^3} \phi^{5/2} \leq \sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^{5/2}$$

Proof. The functions $\lambda_\tau(x)$ in (62) are non-negative and satisfy

$$\sum_{\substack{\tau \in \mathbb{Z}^3 \\ |\tau| = \sqrt{3}}} \lambda_\tau(x) = 1$$

and that $\int_{[-1/2, 1/2]^3} \lambda_\tau(x) dx = 1/8$ for all $\tau \in \mathbb{Z}^3$ with $|\tau| = \sqrt{3}$. We thus get from the inequality in Lemma 12.1 that for all $\mu \in \{(1/2, 1/2, 1/2)\} + \mathbb{Z}^3$

$$\frac{1}{8} \sum_{\substack{\tau \in \mathbb{Z}^3 \\ |\tau| = \sqrt{3}}} S(\mu + \tau/2)^\beta \geq \int_{\{\mu\} + [-1/2, 1/2]^3} \phi(x)^\beta dx$$

$$\geq \frac{1}{8} \sum_{\substack{\tau \in \mathbb{Z}^3 \\ |\tau| = \sqrt{3}}} S(\mu + \tau/2)^\beta - C \left(\sum_{\substack{\tau_1, \tau_2 \in \mathbb{Z}^3 \\ |\tau_1| = \sqrt{3} \\ |\tau_2| = \sqrt{3}}} (S(\mu + \tau_1/2) - S(\mu + \tau_2/2))^2\right)^{1/2} \sum_{\substack{\tau \in \mathbb{Z}^3 \\ |\tau| = \sqrt{3}}} S(\mu + \tau/2)^{\beta-1}$$

$$\geq \frac{1}{8}(1 - \delta) \sum_{\substack{\tau \in \mathbb{Z}^3 \\ |\tau| = \sqrt{3}}} S(\mu + \tau/2)^\beta - C\delta^{-(\beta-1)} \left(\sum_{\substack{\tau_1, \tau_2 \in \mathbb{Z}^3 \\ |\tau_1| = \sqrt{3} \\ |\tau_2| = \sqrt{3}}} (S(\mu + \tau_1/2) - S(\mu + \tau_2/2))^2\right)^{\beta/2}.$$

If we sum these inequalities over μ (i.e., over cubes), use that each point in $\mathbb{Z}^3$ is the corner of 8 different cubes, and that $\sum_\mu b_\mu^{\beta/2} \leq (\sum_\mu b_\mu)^{\beta/2}$, when $b_\mu \geq 0$, we obtain the first inequality of the lemma.

To arrive at the second inequality we instead use the Cauchy-Schwarz estimate

$$\left(\sum_{\substack{\tau_1, \tau_2 \in \mathbb{Z}^3 \\ |\tau_1| = \sqrt{3} \\ |\tau_2| = \sqrt{3}}} (S(\mu + \tau_1/2) - S(\mu + \tau_2/2))^2\right)^{1/2} \sum_{\substack{\tau \in \mathbb{Z}^3 \\ |\tau| = \sqrt{3}}} S(\mu + \tau/2)^{\beta-1} \leq$$

$$\delta \sum_{\substack{\tau_1, \tau_2 \in \mathbb{Z}^3 \\ |\tau_1| = \sqrt{3} \\ |\tau_2| = \sqrt{3}}} (S(\mu + \tau_1/2) - S(\mu + \tau_2/2))^2 + C\delta^{-1} \sum_{\substack{\tau \in \mathbb{Z}^3 \\ |\tau| = \sqrt{3}}} S(\mu + \tau/2)^{2\beta-2}.$$

For $\beta = 5/2$ we have $2\beta - 2 = 3$. The second inequality in the lemma then follows by summing over μ as above, possibly redefining δ, and using that

$$\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^3 \leq \Big(\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^6\Big)^{1/4} \Big(\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^2\Big)^{3/4}.$$

$\square$

12.3 THEOREM (The Sobolev inequality for T).
There exists a constant $C > 0$ such that for all maps $S : \mathbb{Z}^3 \to \mathbb{R}$ that vanish outside some finite set we have

$$\Big(\sum_{\sigma \in \mathbb{Z}^3} |S(\sigma)|^6\Big)^{1/3} \leq CT(S).$$

Proof. Since $T(S) \geq T(|S|)$ it is enough to consider only non-negative maps S. If we use the first inequality in Lemma 12.2 with $\beta = 6$ and $\delta = 1/2$ we obtain that

$$\sum_{\sigma \in \mathbb{Z}^3} |S(\sigma)|^6 \leq 2 \int \phi(x)^6 dx + CT(S)^3.$$

Since $\phi : \mathbb{R}^3 \to \mathbb{R}$ is a C^1 function of compact support we may use the standard Sobolev inequality on $\mathbb{R}^3$

$$\int \phi(x)^6 dx \leq C \left(\int |\nabla\phi(x)|^2 dx\right)^3 = CT(S)^3.$$

$\square$

If S vanishes outside a finite set we get from the Sobolev inequality and the second inequality in Lemma 12.2 that

$$\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^{5/2} - \delta T(S) - C\delta^{-7}\Big(\sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^2\Big)^3 \leq \int_{\mathbb{R}^3} \phi^{5/2} \leq \sum_{\sigma \in \mathbb{Z}^3} S(\sigma)^{5/2}. \tag{64}$$

12.1   Application of the lattice approximation to the situation in Theorem 5.2

We shall use the above results for the map

$$S_0(\sigma) = S_0^\Psi(\sigma) = \ell^{-1}(\sqrt{\langle n_\sigma\rangle + 1} - 1).$$

The expression $T(S_0)$ is then exactly the term that appears in Theorem 5.2 on localizing into small cubes. Note that $S_0(\sigma) \leq \ell^{-1}\sqrt{\langle n_\sigma\rangle}$. Let $\phi : \mathbb{R}^3 \to \mathbb{R}$ be the function corresponding to S_0 as constructed in (61). Then from (63) and Lemma 12.2 we get

$$T(S_0) = \int (\nabla\phi)^2 \quad \text{and} \quad \ell^2 \int \phi^2 \leq \sum_{\sigma \in \mathbb{Z}^3} \ell^2 S_0(\sigma)^2 \leq \sum_{\sigma \in \mathbb{Z}^3} \langle n_\sigma\rangle \leq N. \tag{65}$$

Moreover, we get for all $0 < \delta$ that

$$
\begin{aligned}
\sum_{\sigma \in \mathbb{Z}^3} \langle n_\sigma \rangle^{5/4} \ell^{-3/4} &\leq (1-\delta) \sum_{\sigma \in \mathbb{Z}^3} S_0(\sigma)^{5/2} \ell^{7/4} + C\delta^{-3/2} \ell^{-3/4} (L/\ell)^3 \\
&\leq (1-\delta)\ell^{7/4} \int \phi^{5/2} + \delta T(S_0) + C\delta^{-7} \ell^8 \Big(\sum_{\sigma \in \mathbb{Z}^3} \ell^2 S_0(\sigma)^2 \Big)^3 + C\delta^{-3/2} \ell^{-3/4} (L/\ell)^3 \\
&\leq (1-\delta)\ell^{7/4} \int \phi^{5/2} + \delta T(S_0) + C\delta^{-7} \ell^8 N^3 + C\delta^{-3/2} \ell^{-3/4} (L/\ell)^3, \qquad (66)
\end{aligned}
$$

where we have used firstly that $\langle n_\sigma \rangle \neq 0$ for at most $(L/\ell)^3$ different points σ and secondly the inequality (64) with δ replaced by $\delta \ell^{-7/4}$. Likewise we get from the Sobolev inequality Theorem 12.3

$$
\begin{aligned}
\sum_{\sigma \in \mathbb{Z}^3} \langle n_\sigma \rangle^{5/3} \ell^{-1/3} &\leq C \sum_{\sigma \in \mathbb{Z}^3} \ell^3 S_0(\sigma)^{10/3} + C\ell^{-1/3} (L/\ell)^3 \\
&\leq C \Big(\sum_{\sigma \in \mathbb{Z}^3} S_0(\sigma)^6 \Big)^{1/3} \Big(\ell^{5/2} \sum_{\sigma \in \mathbb{Z}^3} \ell^2 S_0(\sigma)^2 \Big)^{2/3} + C\ell^{-1/3} (L/\ell)^3 \\
&\leq CT(S_0)(N^{2/5}\ell)^{5/3} + C\ell^{-1/3} (L/\ell)^3. \qquad (67)
\end{aligned}
$$

Finally, note that if we define $\widetilde{\Phi}(x) = \ell^{-1/2} \phi(x/\ell)$ we find that

$$
\int (\nabla \widetilde{\Phi})^2 = \int (\nabla \phi)^2, \quad \int \widetilde{\Phi}^{5/2} = \ell^{7/4} \int \phi^{5/2}, \quad \int \widetilde{\Phi}^2 = \ell^2 \int \phi^2. \qquad (68)
$$

13   Completing the proof of Dyson's formula Theorem 2.1

In this final section we shall combine all the previous results to conclude Theorem 2.1. From Theorems 4.2, 5.2, 11.1, and (65), (66), (67), and (68) we obtain, under the assumptions that $C_0 N \ell^3 \leq \varepsilon^3$ and $\varepsilon^{-1} t^{-4} \ell \leq C_0^{-1}$, that

$$
E(N) \geq \inf_{\widetilde{\Phi}} \Big(A \int \big(\nabla \widetilde{\Phi} \big)^2 - B \int \widetilde{\Phi}^{5/2} \Big) - DN^{7/5},
$$

where the infimum is over all functions $\widetilde{\Phi} \geq 0$, such that $\int \widetilde{\Phi}^2 \leq N$ and

$$
\begin{aligned}
A &= (\gamma\widetilde{\gamma}\gamma_{\varepsilon,t}/2 - \gamma\widetilde{\gamma}\gamma_{\varepsilon,t}^{-1/4} I_0 \delta - C\varepsilon^{1/6} - CK_2(\varepsilon,t,N,\ell)) \\
B &= (1-\delta)\gamma\widetilde{\gamma}(\gamma_{\varepsilon,t}^{-1/4} I_0 + K_1(\varepsilon,t,N,\ell)) \\
D &= C\Big(t^{-2}(N^{1/5}L)^{-2} + t^{-4}(N^{2/5}\ell)^{-1} + (N^{1/5}L)^3(N^{2/5}\ell)^{-5} \\
&\quad + t^{-6}(N^{1/5}\ell)^{-1}N^{-1/5} + \varepsilon^{-1}t^{-8}N^{-2/5} \\
&\quad + \gamma\widetilde{\gamma}(\gamma_{\varepsilon,t}^{-1/4} I_0 + K_1(\varepsilon,t,N,\ell))\delta^{-7}(N^{2/5}\ell)^8 N^{-8/5} \\
&\quad + \gamma\widetilde{\gamma}(\gamma_{\varepsilon,t}^{-1/4} I_0 + K_1(\varepsilon,t,N,\ell))\delta^{-3/2}(N^{1/5}L)^3(N^{2/5}\ell)^{-15/4} N^{-1/2} \\
&\quad + (\varepsilon^{1/6} + K_2(\varepsilon,t,N,\ell))(N^{2/5}\ell)^{-5}(N^{1/5}L)^3 N^{-2/3} \Big).
\end{aligned}
$$

We have used that $\sum_\sigma \nu_\sigma = N$ and $\sum_{\sigma,\, \nu_\sigma \neq 0} \ell^{-2} \leq L^3/\ell^5$.

We shall show that as $N \to \infty$ we can choose $\varepsilon, t, \delta \to 0$ and $N^{2/5}\ell, N^{1/5}L \to \infty$ in such a way that $A \to 1/2$, $B \to I_0$, $D \to 0$, $\varepsilon^{-3}N\ell^3 \to 0$, $\varepsilon^{-1}t^{-4}\ell \to 0$, and $\ell < L$.

Note that from (7) and (21) the limits of A and B will follow if we can prove that $K_1, K_2 \to 0$. The error term D is of the form

$$D = Ct^{-2}(N^{1/5}L)^{-2} + Ct^{-4}(N^{2/5}\ell)^{-1} + C(N^{1/5}L)^3(N^{2/5}\ell)^{-5} + K_3$$

where K_3 is a finite sum of terms of the form

$$C\delta^{-a}\varepsilon^{-b}t^{-c}(N^{2/5}\ell)^d(N^{1/5}L)^e N^{-f}, \tag{69}$$

where $f > 0$. Recall that K_1 and K_2 were sums of expressions of the same form. Note that $\varepsilon^{-3}N\ell^3 = \varepsilon^{-3}(N^{2/5}\ell)^3 N^{-1/5}$, $\varepsilon^{-1}t^{-4}\ell = \varepsilon^{-1}t^{-4}(N^{1/5}\ell)N^{-1/5}$, and $\ell/L = (N^{2/5}\ell)(N^{1/5}L)^{-1}N^{-1/5}$ (which is required to be less than 1) are again all of the form (69).

Now first choose $N^{2/5}\ell \to \infty$ in such a way that $(N^{2/5}\ell)^d N^{-f} \to 0$ for all the occurring terms of the form (69). Then choose $N^{1/5}L \to \infty$ in such a way that $C(N^{1/5}L)^3(N^{2/5}\ell)^{-5} \to 0$ and $(N^{2/5}\ell)^d(N^{1/5}L)^e N^{-f} \to 0$ for all the terms of the form (69). Finally choose $\varepsilon, t, \delta \to 0$ in such a way that all the terms of the form (69) and the first two terms in D still go to zero. Hence we have achieved all the limits as claimed.

Dyson's formula now follows since by scaling we have that

$$A \int \left(\nabla\widetilde{\Phi}\right)^2 - B \int \widetilde{\Phi}^{5/2} = (2A)^{-3/5}(B/I_0)^{4/5}N^{7/5}\left(\frac{1}{2}\int(\nabla\Phi)^2 - I_0\int\Phi^{5/2}\right),$$

where

$$\Phi(x) = (2AI_0/B)^{6/5}N^{-8/10}\widetilde{\Phi}\left((2AI_0/B)^{4/5}N^{-1/5}x\right)$$

satisfies $\int \Phi^2 = N^{-1}\int\widetilde{\Phi}^2 \leq 1$ if $\int\widetilde{\Phi}^2 \leq N$.

A Appendix: Localization of large matrices

The following theorem allows us to reduce a big Hermitean matrix, $\mathcal{A}$, to a smaller principal submatrix without changing the lowest eigenvalue very much. The proof can be found in [LSo].

A.1 THEOREM (Localization large matrices). *Suppose that $\mathcal{A}$ is an $N \times N$ Hermitean matrix and let $\mathcal{A}^k$, with $k = 0, 1, \ldots, N-1$, denote the matrix consisting of the kth supra- and infra-diagonal of $\mathcal{A}$. Let $\psi \in \mathbf{C}^N$ be a normalized vector and set $d_k = (\psi, \mathcal{A}^k\psi)$ and $\lambda = (\psi, \mathcal{A}\psi) = \sum_{k=0}^{N-1} d_k$. ($\psi$ need not be an eigenvector of $\mathcal{A}$.)*

Choose some positive integer $M \leq N$. Then, with M fixed, there is some $n \in [0, N-M]$ and some normalized vector $\phi \in \mathbf{C}^N$ with the property that $\phi_j = 0$ unless $n+1 \leq j \leq n+M$ (i.e., ϕ has length M) and such that

$$(\phi, \mathcal{A}\phi) \leq \lambda + \frac{C}{M^2}\sum_{k=1}^{M-1} k^2|d_k| + C\sum_{k=M}^{N-1}|d_k|, \tag{70}$$

where $C > 0$ is a universal constant. (Note that the first sum starts with $k = 1$.)

B   Appendix: Localization of the kinetic energy

Our goal here is to prove a certain lower bound on the many body kinetic energy $\sum_{i=1}^{N} -\Delta_i$ acting on the symmetric tensor product space $\bigotimes_S^N L^2(\mathbb{R}^3)$. In order to state the bound we need to introduce some more notation. Let X_0 denote the characteristic function of the cube $[-\ell/2, \ell/2]^3$, in $\mathbb{R}^3$. Let X_z be the characteristic function of the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$, i.e., $X_z(x) = X_0(x - \ell z)$. Let $\mathcal{P}_z$ denote the projection onto the subspace of $L^2(\{z\ell\}+[-\ell/2, \ell/2]^3)$ consisting of functions orthogonal to constants. We shall consider $\mathcal{P}_z$ as a projection in $L^2(\mathbb{R}^3)$. Let $-\Delta_{\text{Neu}}^{(z)}$ be the Neumann Laplacian for the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$. Let $a_0^*(z)$ be the creation operator

$$a_0^*(z) = a^*(\ell^{-3/2} X_z),$$

i.e., the operator creating the constant in the cube $\{z\ell\} + [-\ell/2, \ell/2]^3$. Note that as before $a_0^*(z)$ acts in the Fock space $\bigoplus_{N=0}^{\infty} \bigotimes_S^N L^2(\mathbb{R}^3)$. Products of the form $a_0^*(z)a_0(z')$ or $a_0(z')a_0^*(z)$ are however bounded operators on the space $\bigotimes_S^N L^2(\mathbb{R}^3)$. Let for all $z \in \mathbb{R}^3$ the function $\chi_z \in C_0^\infty(\{z\ell\} + (-\ell/2, \ell/2)^3)$ be such that $\|\partial^\alpha \chi_z\|_\infty \le C(\ell t)^{-|\alpha|}$ and $\|\partial^\alpha \sqrt{1 - \chi_z^2}\|_\infty \le C(\ell t)^{-|\alpha|}$ for some t with $0 < t < 1$ and all multi-indices α with $|\alpha| \le 3$.

We can now state the operator inequality we would like to prove.

B.1 THEOREM (Kinetic energy localization).
Let $\Omega \subset \mathbb{R}^3$. Let $w_1, \ldots, w_r \in \mathbb{R}^3$ and $\beta_1, \ldots, \beta_r > 0$ be such that $X_{w_j} X_0 = 0$ for all $j = 1, \ldots, r$ and such that for all $v \in \mathbb{R}^3$ we have that

$$\sum_{j=1}^{r} \beta_j (w_j, v)^2 \le v^2.$$

Then for all $0 < s < t < 1$ and all $\varepsilon > 0$ we have

$$\left(1 + \varepsilon + C(s/t)t^{-2} + Cs^{1/2} + Cs\left(\sum_{j=1}^{r} \beta_j\right)^{1/2}\right) \sum_{i=1}^{N} -\Delta_i$$

$$\ge \int_\Omega \Big[\sum_{i=1}^{N} \mathcal{P}_z^{(i)} \chi_z^{(i)} \frac{(-\Delta_i)^2}{-\Delta_i + (\ell s)^{-2}} \chi_z^{(i)} \mathcal{P}_z^{(i)} + \varepsilon(-\Delta_{i,\text{Neu}}^{(z)}) \tag{71}$$

$$+ \sum_{j=1}^{r} \frac{\beta_j}{\ell^2}\left(\sqrt{a_0^*(z+w_j)a_0(z+w_j) + 1/2} - \sqrt{a_0^*(z)a_0(z) + 1/2}\right)^2\Big] dz - \sum_{j=1}^{r} \frac{\beta_j}{\ell^2}\text{vol}(\Omega).$$

Here all operators are considered in the sense of quadratic forms.

Proof. By rescaling we may consider $\ell = 1$.

Note first that on the quadratic form domain of the Laplacian $-\Delta$ on $\mathbb{R}^3$ we have

$$\int_\Omega (-\Delta_{\text{Neu}}^{(z)}) dz \le \int_{\mathbb{R}^3} (-\Delta_{\text{Neu}}^{(z)}) dz = -\Delta.$$

in the sense of quadratic forms.

Let $f_s : \mathbb{R}^3 \to \mathbb{R}^3$ be the function $f_s(p) = p^2/(p^2 + s^{-2})$ for some $s > 0$. Then for all $u \in L^2(\mathbb{R}^3)$ we have

$$(2\pi)^{-3} \int f_s(p)|\hat{u}(p)|^2 dp = \int \overline{u(x)} \left(\frac{-\Delta}{-\Delta + s^{-2}} u \right)(x)dx.$$

It follows that for all $u \in L^2(\mathbb{R}^3)$ we have

$$(2\pi)^{-6} \int f_s * |\hat{X}|^2(p)|\hat{u}(p)|^2 dp = \iint \overline{u(x)} X_z(x) \left(\frac{-\Delta}{-\Delta + s^{-2}} (X_z u) \right)(x) dx dz.$$

B.2 LEMMA. *We have*

$$\|f_s - (2\pi)^{-3} f_s * |\hat{X}|^2\|_\infty \le Cs^{1/2}.$$

Proof. We calculate

$$|\hat{X}(p)|^2 = \left(\frac{2\sin(p_1/2)}{p_1} \right)^2 \left(\frac{2\sin(p_2/2)}{p_2} \right)^2 \left(\frac{2\sin(p_3/2)}{p_3} \right)^2 .$$

In particular $\int_{|p|>r} |\hat{X}(p)|^2 dp \le Cr^{-1}$ for all $r > 0$. Since $(2\pi)^{-3} \int |\hat{X}|^2(p)dp = 1$, $\|f_s\|_\infty \le 1$, and $\|\nabla f_s\|_\infty \le Cs$ we have

$$
\begin{aligned}
\left| f_s(p) - (2\pi)^{-3} f_s * |\hat{X}|^2(p) \right| &\le (2\pi)^{-3} \int_{|q|<r} |f_s(p) - f_s(p-q)||\hat{X}(q)|^2 dq \\
&+ (2\pi)^{-3} \int_{|q|>r} |f_s(p) - f_s(p-q)||\hat{X}(q)|^2 dq \le Csr + Cr^{-1}.
\end{aligned}
$$

The result follows from choosing $r = s^{-1/2}$. $\qquad\square$

We now write

$$
\begin{aligned}
p^2 &= (2\pi)^{-3} p^2 f_s * |\hat{X}|^2(p) + p^2 \left(f_s(p) - (2\pi)^{-3} f_s * |\hat{X}|^2(p) \right) + p^2(1 - f_s(p)) \\
&\ge (2\pi)^{-3} p^2 f_s * |\hat{X}|^2(p) - Cs^{1/2} p^2 + p^2(1 - f_s(p)).
\end{aligned}
$$

For all $u \in L^2(\mathbb{R}^3)$ we have

$$(2\pi)^{-6} \int |\hat{u}(p)|^2 p^2 f_s * |\hat{X}|^2(p)dp = \sum_{i=1}^{3} \iint \overline{\partial_i u(x)} X_z(x) \frac{-\Delta}{-\Delta + s^{-2}} (X_z \partial_i u)(x) dx dz.$$

In other words we have the operator inequality

$$-\Delta \ge \int \mathcal{A}_z dz + \frac{-\Delta s^{-2}}{-\Delta + s^{-2}} - Cs^{1/2}(-\Delta), \tag{72}$$

where the operator

$$\mathcal{A}_z = \sum_{i=1}^{3} -\partial_i X_z \frac{-\Delta}{-\Delta + s^{-2}} X_z \partial_i$$

is defined as giving the positive quadratic form

$$(u, \mathcal{A}_z u) = \sum_{i=1}^{3} \int \overline{\partial_i u(x)} X_z(x) \frac{-\Delta}{-\Delta + s^{-2}} (X_z \partial_i u)(x) dx$$

with domain $H^1(\{z\} + [-1/2, 1/2]^3)$. With the similar notation the operator $\sum_{i=1}^{3} -\partial_i X_z \partial_i$ is nothing but the Neumann Laplacian $-\Delta_{\text{Neu}}^{(z)}$.

B.3 LEMMA. *Given* $\theta \in C^\infty(\{z\} + [-1/2, 1/2]^3)$ *such that* θ *is constant near the boundary of the cube* $\{z\} + [-1/2, 1/2]^3$. *Assume moreover that* $\|\partial^\alpha \theta\|_\infty \leq C|t|^{-|\alpha|}$ *for some* t *with* $s < t$ *and all multi-indices* α *with* $|\alpha| \leq 3$. *Then*

$$[[\mathcal{A}_z, \theta], \theta] \geq -C(s/t)(-\Delta_{\text{Neu}}^{(z)}) - C(s/t)t^{-2}X_z.$$

Proof. We calculate

$$\left[-\partial_i X_z \frac{-\Delta}{-\Delta + s^{-2}} X_z \partial_i, \theta\right] = -\partial_i X_z \frac{-\Delta}{-\Delta + s^{-2}}(\partial_i \theta) - \partial_i X_z \left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right] X_z \partial_i$$
$$- (\partial_i \theta) \frac{-\Delta}{-\Delta + s^{-2}} X_z \partial_i$$

and

$$\left[\left[-\partial_i X_z \frac{-\Delta}{-\Delta + s^{-2}} X_z \partial_i, \theta\right], \theta\right] = -2\partial_i X_z \left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right](\partial_i \theta) - 2(\partial_i \theta)\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right] X_z \partial_i$$
$$- 2(\partial_i \theta) \frac{-\Delta}{-\Delta + s^{-2}}(\partial_i \theta) - \partial_i X_z \left[\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right], \theta\right] X_z \partial_i.$$

We also calculate

$$\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right] = s^{-2} \frac{1}{-\Delta + s^{-2}}[-\Delta, \theta]\frac{1}{-\Delta + s^{-2}}$$

and

$$\left[\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right], \theta\right] = s^{-2} \frac{1}{-\Delta + s^{-2}}[[-\Delta, \theta], \theta]\frac{1}{-\Delta + s^{-2}}$$
$$+ 2s^{-2} \frac{1}{-\Delta + s^{-2}}[-\Delta, \theta]\frac{1}{-\Delta + s^{-2}}[\theta, -\Delta]\frac{1}{-\Delta + s^{-2}}.$$

Hence

$$\left\|\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right]\right\| \leq Cs/t \quad \text{and} \quad \left\|\left[\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right], \theta\right]\right\| \leq C(s/t)^2$$

Likewise

$$\left\|\left[\left[\frac{-\Delta}{-\Delta + s^{-2}}, \partial_i \theta\right], \partial_i \theta\right]\right\| \leq C(s/t)^2 t^{-2}.$$

Using these estimates we find that

$$\partial_i X_z \left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right](\partial_i \theta) + (\partial_i \theta)\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right] X_z \partial_i$$
$$\leq -(t/s)\partial_i X_z \left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right]\left[\frac{-\Delta}{-\Delta + s^{-2}}, \theta\right]^* X_z \partial_i + (s/t)(\partial_i \theta)^2$$
$$\leq -C(s/t)\partial_i X_z \partial_i + C(s/t)t^{-2}X_z$$

and

$$(\partial_i \theta) \frac{-\Delta}{-\Delta + s^{-2}} (\partial_i \theta) = \sum_{j=1}^{3} -\partial_j (\partial_i \theta) \frac{1}{-\Delta + s^{-2}} (\partial_i \theta) \partial_j$$

$$+ \sum_{j=1}^{3} (\partial_j \partial_i \theta) \frac{\partial_j}{-\Delta + s^{-2}} (\partial_i \theta) - \sum_{j=1}^{3} (\partial_i \theta) \frac{\partial_j}{-\Delta + s^{-2}} (\partial_j \partial_i \theta)$$

$$- \sum_{j=1}^{3} (\partial_j \partial_i \theta) \frac{1}{-\Delta + s^{-2}} (\partial_j \partial_i \theta)$$

$$\leq \sum_{j=1}^{3} -\partial_j (\partial_i \theta) \frac{1}{-\Delta + s^{-2}} (\partial_i \theta) \partial_j + C(s/t) t^{-2} X_z$$

$$\leq -C(s/t)^2 \sum_{j=1}^{3} \partial_j X_z \partial_j + C(s/t) t^{-2} X_z.$$

$\square$

With $\eta_z = \sqrt{1 - \chi_z^2}$ we may write

$$\mathcal{A}_z = \tfrac{1}{2} (\eta_z^2 + \chi_z^2) \mathcal{A}_z + \tfrac{1}{2} \mathcal{A}_z (\eta_z^2 + \chi_z^2)$$

$$= \chi_z \mathcal{A}_z \chi_z + \eta_z \mathcal{A}_z \eta_z + \tfrac{1}{2} [[\mathcal{A}_z, \chi_z], \chi_z] + \tfrac{1}{2} [[\mathcal{A}_z, \eta_z], \eta_z]$$

$$\geq \chi_z \frac{(-\Delta)^2}{-\Delta + s^{-2}} \chi_z - C(s/t)(-\Delta_{\text{Neu}}^{(z)}) - C(s/t) t^{-2} X_z.$$

Here we have used that $\chi_z \mathcal{A}_z \chi_z = \chi_z \frac{(-\Delta)^2}{-\Delta + s^{-2}} \chi_z$, where $-\Delta$ is the Laplacian on $\mathbb{R}^3$.

Clearly we have $\mathcal{P}_z \mathcal{A}_z \mathcal{P}_z = \mathcal{A}_z$. Thus

$$\mathcal{A}_z \geq \mathcal{P}_z \chi_z \frac{(-\Delta)^2}{-\Delta + s^{-2}} \chi_z \mathcal{P}_z - C(s/t)(-\Delta_{\text{Neu}}^{(z)}) - C(s/t) t^{-2} \mathcal{P}_z$$

$$\geq \mathcal{P}_z \chi_z \frac{(-\Delta)^2}{-\Delta + s^{-2}} \chi_z \mathcal{P}_z - C(s/t) t^{-2} (-\Delta_{\text{Neu}}^{(z)}),$$

where we have assumed that $t < 1$ and used that $-\Delta_{\text{Neu}}^{(z)} \geq C \mathcal{P}_z$.

We turn now to the term $-\Delta s^{-2} / (-\Delta + s^{-2})$ in (72).

B.4 LEMMA. *For all $u \in L^2(\mathbb{R}^3)$ we have that*

$$\sum_{j=1}^{r} \int_{\mathbb{R}^3} \beta_j |u(x + w_j) - u(x)|^2 \, dx \leq \left(u, \left(\frac{-\Delta s^{-2}}{-\Delta + s^{-2}} + 2 \Big(\sum_{j=1}^{r} \beta_j \Big)^{1/2} s(-\Delta) \right) u \right)$$

Proof. Write $b = 2 \left(\sum_{j=1}^{r} \beta_j \right)^{1/2}$. On one hand we may write

$$\left(u, \left(\frac{-\Delta s^{-2}}{-\Delta + s^{-2}} + bs(-\Delta) \right) u \right) = (2\pi)^{-3} \int |\hat{u}(p)|^2 \left(\frac{p^2 s^{-2}}{p^2 + s^{-2}} + bsp^2 \right) dp.$$

On the other hand we have

$$\sum_{j=1}^{r} \int \beta_j \, |u(x+w_j) - u(x)|^2 \, dx \;=\; \sum_{j=1}^{r} (2\pi)^{-3} \int \beta_j |\hat{u}(p)|^2 |\exp(i(p,w_j)/2) - \exp(-i(p,w_j)/2)|^2 dp$$

$$=\; \sum_{j=1}^{r} (2\pi)^{-3} \int \beta_j |\hat{u}(p)|^2 4 \sin^2((p,w_j)/2) dp.$$

We thus simply have to prove that

$$\frac{p^2 s^{-2}}{p^2 + s^{-2}} + bsp^2 \geq \sum_{j=1}^{r} 4\beta_j \sin^2((p,w_j)/2).$$

If $2|p| < b^{1/2} s^{-1/2}$ we have

$$\frac{p^2 s^{-2}}{p^2 + s^{-2}} \geq \frac{p^2}{bs+1} \geq (1-bs)p^2 \geq \sum_{j=1}^{r} 4\beta_j \sin^2((p,w_j)/2) - bsp^2.$$

If $|p| > b^{1/2} s^{-1/2}$ we have

$$bsp^2 \geq b^2 \geq \sum_{j=1}^{r} 4\beta_j \sin^2((p,w_j)/2).$$

$\square$

Since for all $y \in \mathbb{R}^3$, $(X_{y+\sigma})_{\sigma \in \mathbb{Z}^3}$ is an orthonormal family in $L^2(\mathbb{R}^3)$, we get from Parseval's identity that

$$\int |u(x+w_j) - u(x)|^2 \, dx \geq \sum_{\sigma \in \mathbb{Z}^3} \left| \int X_{y+\sigma}(x)(u(x+w_j) - u(x)) dx \right|^2.$$

If we integrate this over $y \in [0,1]^3$ we obtain

$$\int |u(x+w_j) - u(x)|^2 \, dz \geq \int \left| \int X_z(x) \, (u(x+w_j) - u(x)) \, dx \right|^2 dz.$$

The quadratic form on the right of this inequality corresponds to the operator whose second quantization has the form

$$\int (a_0^*(z+w_j) - a_0^*(z)) \, (a_0(z+w_j) - a_0(z)) dz.$$

It is then clear that the main inequality (71) follows from the following lemma.

B.5 LEMMA. *Let a_1^* and a_2^* be two commuting creation operators. Then*

$$(a_2^* - a_1^*)(a_2 - a_1) \geq \left(\sqrt{a_2^* a_2 + 1/2} - \sqrt{a_1^* a_1 + 1/2} \right)^2 - 1.$$

Proof. We calculate

$$(a_2^* - a_1^*)(a_2 - a_1) = a_2^* a_2 + a_1^* a_1 - (a_2^* a_1 + a_1^* a_2).$$

We have

$$
\begin{aligned}
(a_2^* a_1 + a_1^* a_2)^2 \;&\le\; (a_2^* a_1 + a_1^* a_2)^2 + (a_2^* a_1 - a_1^* a_2)(a_1^* a_2 - a_2^* a_1) \\
&=\; 2a_2^* a_1 a_1^* a_2 + 2a_1^* a_2 a_2^* a_1 = 4a_2^* a_2 a_1^* a_1 + 2a_1^* a_1 + 2a_2^* a_2 \\
&=\; 4(a_2^* a_2 + 1/2)(a_1^* a_1 + 1/2) - 1 \le 4(a_2^* a_2 + 1/2)(a_1^* a_1 + 1/2).
\end{aligned}
$$

Since the square root is an operator monotone function we have that

$$
a_2^* a_1 + a_1^* a_2 \le 2\sqrt{a_2^* a_2 + 1/2}\sqrt{a_1^* a_1 + 1/2}.
$$

Hence

$$
\begin{aligned}
(a_2^* - a_1^*)(a_2 - a_1) \;&\ge\; a_2^* a_2 + a_1^* a_1 - 2\sqrt{a_2^* a_2 + 1/2}\sqrt{(a_1^* a_1 + 1/2}} \\
&=\; \left(\sqrt{a_2^* a_2 + 1/2} - \sqrt{a_1^* a_1 + 1/2}\right)^2 - 1.
\end{aligned}
$$

$\square$

$\square$

We shall use Theorem B.1 with $w_1, w_2, \ldots, w_r$ being the vectors $\sigma \in \mathbb{Z}^3$ satisfying that $|\sigma|^2 = 2$ or $|\sigma|^2 = 3$. Note that there is a total of 20 such vectors. We define

$$
\beta_\sigma = \begin{cases} \frac{1}{12}, & |\sigma|^2 = 2 \\ \frac{1}{24}, & |\sigma|^2 = 3 \end{cases}
$$

We then have for all $v \in \mathbb{R}^3$ that

$$
\sum_{\substack{\sigma \in \mathbb{Z}^3 \\ |\sigma|=\sqrt{2}\ \text{or}\ |\sigma|=\sqrt{3}}} \beta_\sigma (v \cdot \sigma)^2 = \sum_{\substack{\sigma \in \mathbb{Z}^3 \\ |\sigma|=\sqrt{2}}} \frac{1}{12}(v \cdot \sigma)^2 + \sum_{\substack{\sigma \in \mathbb{Z}^3 \\ |\sigma|=\sqrt{3}}} \frac{1}{24}(v \cdot \sigma)^2 = v^2.
$$
